# **MEN'S REPRODUCTIVE HEALTH: FINDINGS FROM THE DEMOGRAPHIC AND HEALTH SURVEYS, 1995-2004**

## **DHS COMPARATIVE REPORTS 17**

**JUNE 2009**

This publication was produced for review by the United States Agency for International Development (USAID). It was prepared by Kiersten Johnson and Yuan Gu of ICF Macro.

MEASURE DHS assists countries worldwide in the collection and use of data to monitor and evaluate population, health, and nutrition programs. Additional information about the MEASURE DHS project can be obtained by contacting Demographic and Health Research Division, ICF Macro, 11785 Beltsville Drive, Suite 300, Calverton, MD 20705 (telephone: 301-572-0200; fax: 301-572-0999; e-mail: [reports@macrointernational.com](mailto:reports@macrointernational.com); internet: [www.measuredhs.com](http://www.measuredhs.com)).

The main objectives of the MEASURE DHS project are:

- to provide decisionmakers in survey countries with information useful for informed policy choices;
- to expand the international population and health database;
- to advance survey methodology; and
- to develop in participating countries the skills and resources necessary to conduct high-quality demographic and health surveys.

## Preface

One of the most significant contributions of the MEASURE DHS program is the creation of an internationally comparable body of data on the demographic and health characteristics of populations in developing countries. The *DHS Comparative Reports* series examines these data across countries in a comparative framework. The *DHS Analytical Studies* series focuses on specific topics. The principal objectives of both series are to provide information for policy formulation at the international level and to examine individual country results in an international context. Whereas *Comparative Reports* are primarily descriptive, *Analytical Studies* have a more analytical approach.

The *Comparative Reports* series covers a variable number of countries, depending on the availability of data sets. Where possible, data from previous DHS surveys are used to evaluate trends over time. Each report provides detailed tables and graphs organized by region. Survey-related issues such as questionnaire comparability, survey procedures, data quality, and methodological approaches are addressed as needed.

The topics covered in *Comparative Reports* are selected by MEASURE DHS staff in conjunction with the U.S. Agency for International Development. Some reports are updates of previously published reports.

It is anticipated that the availability of comparable information for a large number of developing countries will enhance the understanding of important issues in the fields of international population and health by analysts and policymakers.

Ann Way  
Project Director

## Executive Summary

This report documents both socioeconomic and demographic characteristics of male respondents to the DHS surveys, as well as male attitudes, preferences, and behaviors relating to contraception, fertility, and health in 40 developing countries.

This report shows large regional variations in the reproductive preferences and behavior of men for both ever-married men and never-married men. A key finding of this report is that in all countries, never-married men (mostly youth age 15-24) are far more likely to know about modern contraceptive methods (particularly condoms) than to engage in sexual activity. This combination of knowledge and behavior suggests that there is currently a good foundation for youth-focused family planning and sexual health programs in most countries.

Another contribution of this report is its analysis of key indicators by the wealth index. While the relationship between wealth and outcomes of interest is typically in the expected direction, the tables presented here allow for a closer investigation of the gradients of inequality for each outcome. For example, the variation in knowledge of contraceptive methods among never-married men by the wealth index is minimal in Malawi but considerable in Guinea. These results are useful in identifying subpopulations that would obtain the most benefit from programmatic interventions.

This report also presents comparable data on men's attitudes about gender roles, men's communication with their spouses about important health issues, data on men's health-related behaviors regarding their own health, and men's knowledge of child health issues. An analysis of men's experience of symptoms of sexually transmitted infections (STIs) according to gender attitudes suggests that gender attitudes do matter for men's health outcomes as well as women's. The data show considerable variation both within and across regions in levels of couple communication about important health issues like HIV and family planning. This kind of country-specific information provides important guidance for program implementation. Similarly, data on men's own health-related behaviors such as smoking allow policymakers to pinpoint where to target resources for interventions. The data in this report documenting the large variation in men's knowledge of how to care for a child with diarrhea indicate that there is considerable need in some countries for the education of fathers regarding how to care for a sick child, especially where orphaning is prevalent.

A trends analysis in several countries demonstrates that improvements in important social indicators, such as education, and health-related behaviors, such as engaging in higher-risk sexual activity, can and do change over time, and often for the better. Nevertheless, continued efforts are required to maintain progress towards sustainable population and health goals for men and their families.

# 1 Introduction

Survey activities over the past three decades have documented basic demographic indicators in many developing countries, thus permitting cross-country comparisons. Data from the Demographic and Health Surveys (DHS) program alone has led to over 42 published comparative reports involving more than 70 countries. These reports cover a wide range of topics, from household characteristics to women's reproductive preferences to children's health. Despite the significant body of knowledge about women's fertility, fertility preferences, reproductive health, and use of reproductive health services generated by the DHS program, much less is known about the reproductive behavior and preferences of men, men's health or health-related behaviors, and men's access to health care services.

As evidence increasingly points to the importance of men in health and reproductive decisionmaking—for their own health and that of their family members—researchers, policymakers, and program managers are turning their attention to male reproductive preferences, behavior, and involvement in family dynamics and decisionmaking (Greene et al., 2006). Surveys of male populations provide useful information on how men perceive, define, or act out their roles in matters of family planning, fertility, AIDS, and sexually transmitted diseases. The relevance and efficiency of population and health programs could be increased by understanding men's perceptions and preferences. This understanding may lead to developing ways that existing programs could be modified to include men, and to the design of new, male-centered or couples-centered programs.

This report provides simple descriptives of male attitudes, preferences, and behaviors relating to contraception, fertility, and health in 40 countries of sub-Saharan Africa (SSA), North Africa/West & Central Asia/Europe (NAAE), South & Southeast Asia (SSEA), and Latin America and the Caribbean (LAC). Data are primarily drawn from the most recent DHS men's surveys conducted since 1995. While both women and men were interviewed for these surveys, this report focuses on the information provided by male respondents.

The first section of the report describes the design and implementation of men's surveys in the DHS program, focusing particularly on the selection procedures for the male sample. The second section discusses the demographic and socioeconomic background characteristics of the men, as well as men's gender-related attitudes. The third section looks at sexual activity and knowledge and use of contraception. The fourth section examines men's fertility and fertility preferences, with a focus on current and ideal family size and desire for additional children. The fifth section looks at three issues that directly affect men's health: smoking, alcohol consumption, and sexually transmitted infections. The sixth and final section assesses men's participation in family life, specifically in terms of communication with their partner about key family issues, and in terms of knowledge of how to care for a sick child. These indicators are examined according to differences in demographic and socioeconomic characteristics and gender-role attitudes. The report concludes with a summary of the major findings.

## 1.1 Sampling

DHS surveys are usually based on a representative sample of households at the national level. The sample is drawn after mapping and household listing operations in the survey areas. Typically, all women age 15-49 years who are usual residents of a household or who slept there the night before the survey are eligible for the individual survey. These sampling procedures are sometimes modified slightly for men: generally, a subsample of selected households is drawn, and men residing in these households are interviewed if they meet certain eligibility criteria. The DHS program includes three types of surveys involving men: 1) men's surveys, which include all eligible men in a specified age range in the selected households, 2) husband surveys, which include only husbands of eligible women in the selected households, and 3) surveys of currently- or ever-married men, which are like men's surveys but include the requirement that the respondent is currently or has ever been married. In men's surveys, the selection criteria for respondents in sample households depend solely on age. All male members of the selected

households who are the appropriate age are interviewed regardless of the outcome of the women's individual interviews. In contrast, the selection criteria for husband surveys draw on supplementary questions in the household questionnaire that determine each woman's marital status. If a woman is in union and her partner lives in the same household, then the partner is retained for an individual male interview. There is no age limit imposed on husbands; however, they are not interviewed if they are married to an ineligible woman (i.e., a woman under age 15 or over age 49). Only one survey included in Table 1.1 is a husband survey (Turkey 1998), one is an ever-married men's survey (Nepal 2001), and three are currently-married men's surveys (Bangladesh 1996/1997, Bangladesh 1999/2000, and Indonesia 2003). The remaining surveys are men's surveys.

Table 1.1 lists the DHS surveys of male populations for all surveys 1995 and later. For each survey, the table shows the year in which the fieldwork was conducted (1995-2004), the eligibility criteria, the total number of male respondents, and the total number of male respondents in union. Although Table 1.1 includes all men's DHS surveys conducted from 1995-2004, the majority of the tables and figures in this report generally include only the most recent survey since 1995 from each country.

Indonesia 2003	2001-2002	15-54	95.1	8,310	8,310
Nepal 2001	2001	15-59	96.1	2,261	2,198
Philippines 2003	2003	15-54	95.1	4,766	2,746
<b>Latin America &amp; Caribbean</b>					
Bolivia 2003	2003	15-64	89.7	6,230	3,823
Bolivia 1998	1998	15-64	89.3	3,780	2,289
Brazil 1996	1996	15-59	74.0	2,950	1,673
Dominican Republic 2002	2002	15-59	80.5	2,833	1,437
Dominican Republic 1996	1996	15-64	80.3	2,279	1,183
Haiti 2000	2000	15-59	92.9	3,171	1,548
Nicaragua 1997/98	1997-1998	15-59	81.4	2,912	1,724
Peru 1996	1996	15-64	84.5	2,487	1,431

Note: Data are for all men except for the following:  
 Turkey 1998 – Husbands of eligible women  
 Bangladesh 1999/00 – Currently married men  
 Bangladesh 1996/97 – Currently married men  
 Indonesia 2003 – Currently married men  
 Nepal 2001 – Ever-married men

The number of men or husbands interviewed in each country depends on the number of households included in the survey, the proportion of those households retained for male interviews, and the eligibility criteria for male respondents. A range of one-twelfth (Peru 1996) to 100 percent (Ghana 2003 and Tanzania 1999) of the households selected for the main survey were retained for the men's survey in each country. In most countries, however, men were interviewed in one-third to one-half of the sampled households. Eligibility criteria for the majority of these surveys use age rather than marital status as the primary criterion for eligibility. Because a few of the surveys used in this analysis use marital status as a criteria for inclusion in the sample, the data are not strictly comparable to those from countries where only age-based criteria determine eligibility. Therefore, all countries using marital status as inclusion criteria will be noted in the tables of this report.

The age limits for men's surveys vary from one country to another. In Senegal 1997, for instance, all men age 20 years and over who lived in the selected households were eligible for an interview, while in Benin 1996, men age 20-64 years were eligible. The age limits for most surveys, however, include men age 15-54 or 15-59, with a scattering of surveys including men age 15-64. For the purposes of this comparative report, the data will be restricted to include only men age 15-54 in the analyses (except for Senegal, where data were not collected for men age 15-19).

As Table 1.1 shows, the response rate for male and husband surveys varies greatly, ranging from 65 percent in Turkey 1998 to 97 percent in Ghana 1998, as does the total number of men interviewed, ranging from 795 in Comoros 1996 to more than 8,000 in Indonesia 2003.

## 1.2 Questionnaires

The men's questionnaires used in DHS surveys are similar to women's questionnaires, but shorter. Usually, men's questionnaires do not include birth histories, questions on child health or mortality, or anthropometric measures. Table 1.2 summarizes the content of the men's questionnaire for each survey.

Table 1.2 Topics included in men's surveys  
Topics included in men's surveys, Demographic and Health Surveys, 1995-2004

Country	Background characteristics			Sexual activity and contraceptive use		Men's health			Men and families	
	Demographic/socioeconomic characteristics	Gender attitudes	Sexual activity	Contraceptive knowledge and use	Men's fertility and preferences	Smoking	Alcohol consumption	STIs	Participation in family dynamics	Knowledge of child health care

Turkey 1998 – Husbands of eligible women  
Indonesia 2003 – Currently married men  
Nepal 2001 – Ever-married men

## ***Demographic and Socioeconomic Characteristics and Gender-Role Attitudes***

All countries include the same core set of information on demographic, social, and economic characteristics such as age, residence, marital status, education, and household wealth. Many of the men's questionnaires also include some questions on the attitudes of men towards women and gender roles. These include whether a man is justified in hitting his wife, whether a woman has the right to refuse sex, and whether a man is justified in retaliating if his wife refuses sex. These will be discussed in more detail later in this report. Also included are questions on who decides how money is spent in the household.

## ***Sexual Activity and Contraceptive Use***

There is an entire section in the men's questionnaire on marriage and sexual activity. In some countries, married respondents are asked about the number of women, other than their wives, that they have had sex with in the past 12 months. If the respondent is single, he is asked how many different sex partners he has had in the past 12 months.

Also included is a section on the knowledge and use of contraceptives. Knowledge of a source for family planning methods is included in most countries. In this report, knowledge of a contraceptive method refers both to spontaneously reported knowledge and to knowledge that resulted from probes by the interviewer. Questions on ever use and current use of a contraceptive method refer to use by the respondent. In addition, in some countries, the respondent is asked whether he and his partner are currently using a method to avoid pregnancy; in others, men who have had sex in the 12 months preceding the survey are asked about the most recently used contraceptive method.

## ***Men's Fertility and Fertility Preferences***

The men's questionnaires determine fertility through a set of questions on the respondent's number of sons and daughters rather than from birth histories. The section on reproduction asks detailed questions on the number of children ever born and the number surviving by sex and residence.

## ***Men's Health***

Regarding men's health issues, topics of sexually transmitted infection, smoking, and use of alcohol may be addressed in the men's questionnaire. In selected countries, men are asked if they have had a sexually transmitted infection, if they have had discharge from their penis, or if they have had a sore or ulcer near their penis in the last 12 months. Men are also asked whether they currently smoke tobacco, and whether they have recently consumed alcohol (usually the reference period is for the past 3 months, but may refer to the past month only).

## ***Men and Families***

Men's participation in family dynamics is assessed by several questions on spousal communication and knowledge of best sick child care practices. The questionnaire covers whether the respondent has discussed with his spouse diverse topics such as the practice of family planning, the ideal number of children the couple would like to have, and ways to prevent HIV/AIDS. Also included are questions on the man's knowledge of ORS (oral rehydration salts, for children with diarrhea), and how much liquid to give a child who is suffering from diarrhea.

## **1.3 Fieldwork Procedures**

In countries with no male interviews, DHS survey teams usually include only female interviewers. In countries with men's surveys, male interviewers are added to the field team to interview the men. Since the men's questionnaire is usually shorter than the women's questionnaire and only a fraction of the selected households are retained for men's interviews, one male interviewer per team is

often sufficient to interview all eligible men. Other field procedures applicable to individual interviews with women, such as obtaining informed consent to conduct the interview, maintaining confidentiality for respondents' answers, and ensuring the privacy of individual interviews, also apply to individual interviews with men.

## 2 Background Characteristics

This section describes the background characteristics that are used in analysis in subsequent chapters. The background characteristic variables are defined and percentages or percent distributions are shown for each country where data are available.

### 2.1 Demographic Background Characteristics

Table 2.1 shows the distribution of all respondents by selected demographic background characteristics: age, residence, and current marital status. Age is a grouped variable with categories for men age 15-19, 20-24, 25-29, 30-39, 40-49, and 50-54. Residence reflects whether the respondent lives in an urban or rural area. The current marital status variable includes the following categories: never married, married to one wife, married to more than one wife, in an informal union, divorced or separated, and widowed.

#### *Age*

Youths age 15-19 constitute 29 percent of respondents in Rwanda and 27 percent of respondents in Zimbabwe, reflecting a particularly young population in these countries compared to other sub-Saharan African countries.<sup>1</sup> In Armenia and Kazakhstan, only about 15-16 percent of male respondents are age 15-19. Haiti and Nicaragua have the highest proportions of young respondents in the Latin America/Caribbean (LAC) region, with 25 percent of respondents in the 15-19 age range.

#### *Residence*

It should be noted that each country defines urban areas differently, making analyses based on residence more useful in intracountry analyses than analyses between countries. That said, the proportion the proportion of men residing in urban areas varies widely within and across regions (Table 2.1). Gabon has the most urbanized population of all countries surveyed, with 80 percent of respondents living in urban areas, while Nepal is the least urban nation at 10 percent. Ethiopia is the least urban nation among sub-Saharan African (SSA) countries surveyed (15 percent). In the three countries of the North Africa/West & Central Asia/Europe (NAAE) region, the majority of men live in urban areas. This is also the case in five of the six countries in the LAC region, with Haiti being the exception: 37 percent of Haitian men live in urban areas.

#### *Marital Status*

In most countries, between 33 percent and 44 percent of respondents have never been married; this figure is as high as 61 percent in Namibia, where men tend to marry later in life, or do not marry at all.

In Malawi, Eritrea, Zambia, and Niger (SSA), in Armenia and Kazakhstan (NAAE), and in Bangladesh and the Philippines (SSEA), 50 percent or more of surveyed men were married to one wife only. In no LAC country were the majority of men in a marital union; rather, in these countries, informal unions are widespread, with up to 34 percent of men in the Dominican Republic engaged in such unions.

Polygyny is highest in francophone West Africa, with 17 percent of men in Guinea and 14-15 percent of men in Mali, Niger, and Burkina Faso having more than one wife. Namibia and Rwanda have

---

<sup>1</sup> Discussion of the age distribution of male respondents excludes consideration of Senegal, Nepal, Indonesia, and Turkey because sampling for those surveys affected their age distribution.

the lowest prevalence of polygyny in the region, at 1-2 percent of men. Outside of the surveyed SSA countries, Haiti has the highest prevalence of polygyny at 7 percent.

The two most urbanized SSA countries also have the highest proportions of divorced or separated men: 13 percent of men in Gabon and 9 percent of men in Cameroon were divorced or separated from their wives or partners at the time of the survey. Percentages of men currently divorced in the remaining SSA countries range from 1 percent (Benin) to 5 percent (Ghana, Tanzania, Uganda, and Namibia). Proportions of divorced men are highest in the Dominican Republic at 14 percent; Nicaragua also has a fairly large proportion of divorced men at 7 percent.

## **2.2 Socioeconomic Background Characteristics**

Table 2.2 shows the distribution of all male respondents by selected socioeconomic background characteristics: education and literacy, occupation, and media exposure. Education that results in literacy is critical for accessing information about health, nutrition, family planning, current events, and other important information that allows people to make informed decisions in their daily lives. The education variable used in this analysis reflects educational attainment, rather than completion: whether the respondent has no formal education, has attained at least some primary education, or has attained at least some secondary education.

Access to mass media is one way of increasing people's knowledge and awareness of what is taking place around them, which may eventually affect their perceptions and behavior. The media variables in this analysis reflect weekly exposure to newspaper and television, and daily exposure to radio.

Occupation is associated with education, lifestyle, and income. The occupational variable distinguishes men who are not working from those who have professional, technical, or managerial occupations; those who have clerical, sales, or service occupations; those who work in agriculture; and those who work in manual and other occupations. The occupational variable reflects the respondent's current occupation, which encompasses work done within the past 12 months. Respondents who have not worked in the past 12 months are considered to be not working.

Table 2.2 Background characteristics of respondents: Socioeconomic characteristics  
 Percent distribution of all men by education and occupation, percentage of men who have been exposed to specific media, and percentage of men who are literate, Demographic and Health Surveys, 1995-2004

## Education

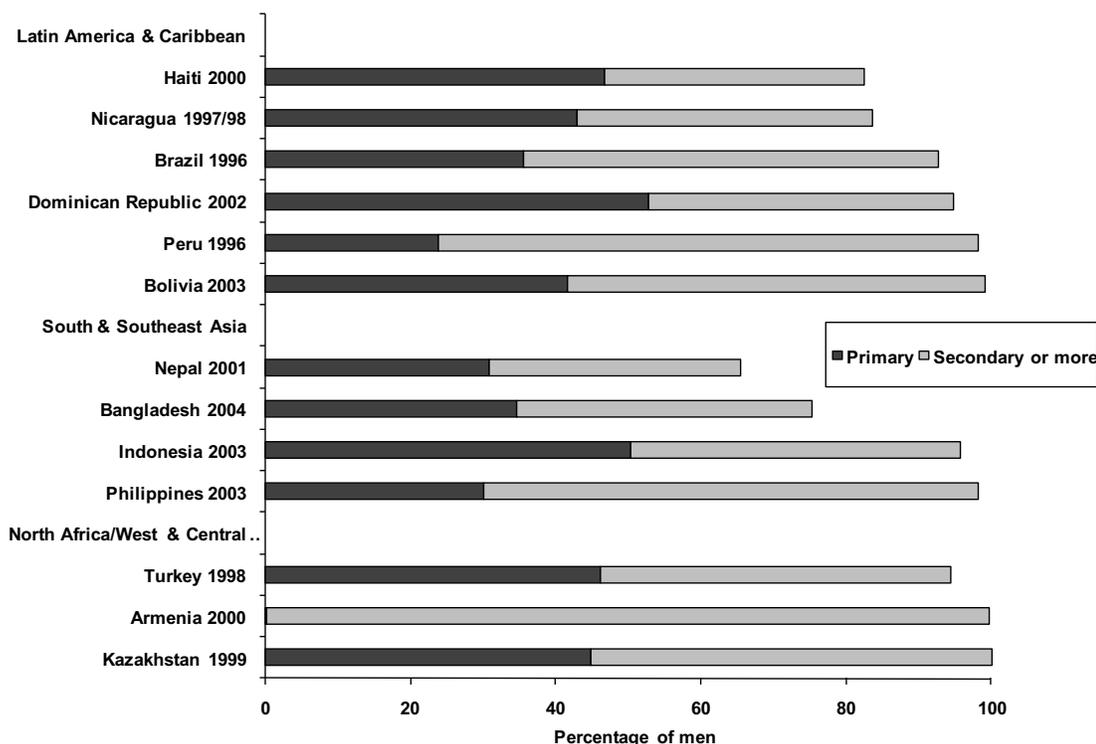

As Table 2.2 above and Figures 2.1a and 2.1b indicate, the average level of education varies within and sub-Saharan Africa (SSA), North Africa/West & Central Asia/Europe (NAAE), South & Southeast Asia (SSEA), and Latin America and the Caribbean (LAC).

Within SSA, four of the top five countries in terms of access to schools are in Anglophone East and Southern Africa (Zimbabwe reported 98 percent of men had attended primary school; Zambia had 95 percent; Uganda and Kenya had 94 percent; and Gabon had 93 percent). The five populations with the least access to schooling are in francophone West Africa: only 47-48 percent of men in Senegal and Guinea have ever attended primary school, and only 36 percent of men in Burkina Faso and Mali, while Niger has the lowest percentage of less than one-third having attended primary school.

**Figure 2.1a Average level of education in SSA countries**

**Figure 2.1b Average level of education in LAC, SSEA, and NAAE countries**

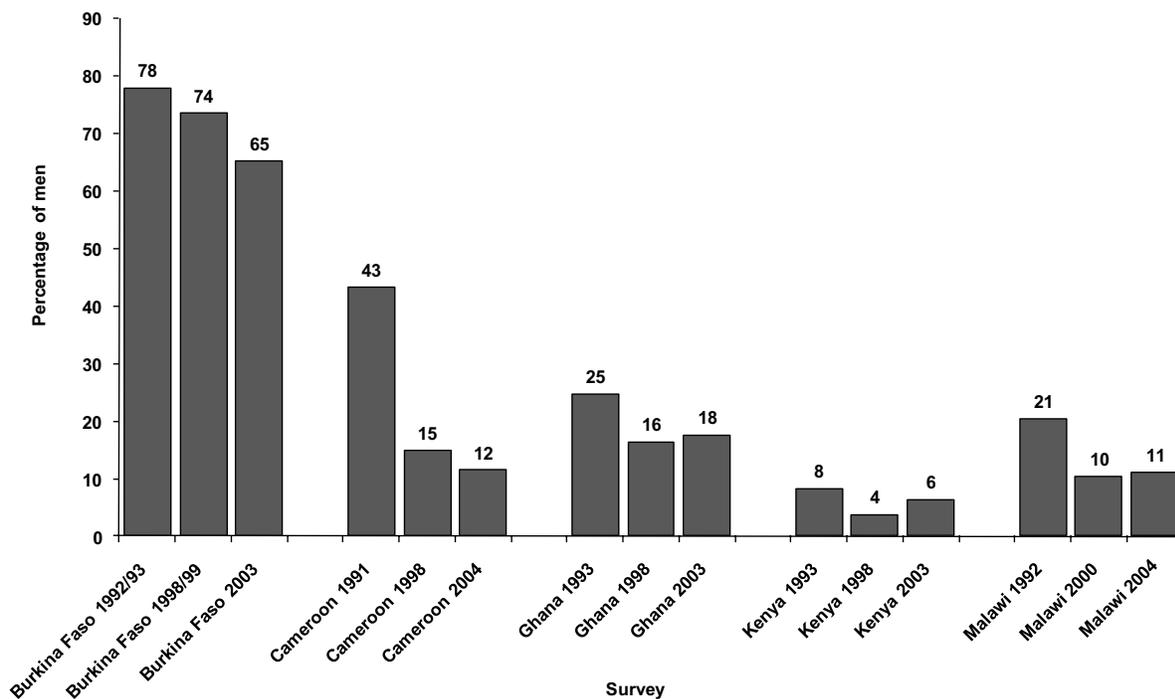

The three countries that represent the NAAE region all have high levels of male primary school attainment. In Armenia, almost all male respondents have completed secondary or higher education, whereas only about half of the men in Kazakhstan and Turkey have attained this level.

Among the four countries that represent SSEA region, levels of education vary widely: over 95 percent of men in the Philippines and Indonesia have attained at least some primary education, while 75 percent of Bangladeshi men and 65 percent of Nepalese men have attained the same. Sixty-eight percent of Filipino men have attained secondary or higher levels of education, the highest in the region, whereas in Nepal, only 35 percent of men have attained any secondary education.

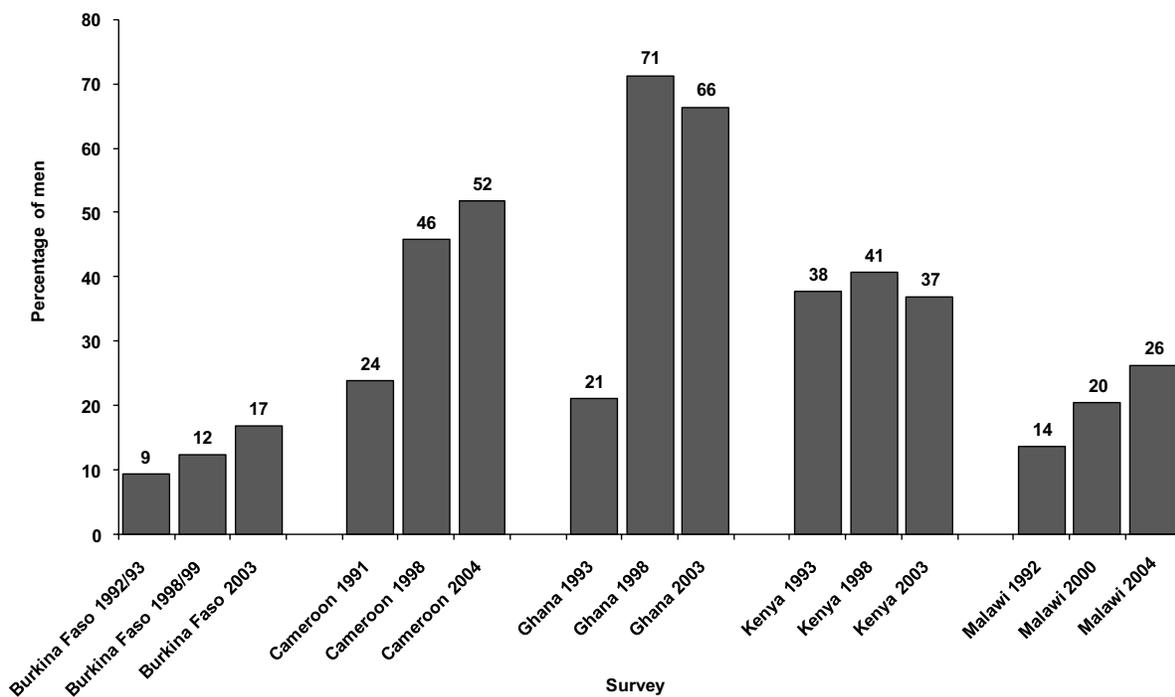

Every country in the LAC region has educated at least 80 percent of the male population age 15-54 to the primary level or higher. Bolivia and Peru have the smallest proportions of men who have not been formally schooled (1-2 percent), while Nicaragua and Haiti have the largest (16-17 percent).

Figures 2.2a and 2.2b show change over time in the percentage of men having no education and the percentage of men having attained secondary or higher education in five countries of SSA that have had at least three men's surveys: Burkina Faso, Cameroon, Ghana, Kenya, and Malawi. Figure 2.2a indicates that, except in Burkina Faso, proportions of men with no education declined from the first survey period to the second, but did not decline further between the second and the third survey. In Burkina Faso, the proportions of uneducated men continued to decline, albeit incrementally. Figure 2.2b demonstrates that proportions of men with secondary or higher levels of education increased with each successive survey in Burkina Faso, Cameroon, and Malawi; plateaued in Kenya; and jumped significantly in Ghana between the first and second survey periods, but declined slightly between the second and third periods.

**Figure 2.2a. Percentage of men with no education in successive surveys in Burkina Faso, Cameroon, Ghana, Kenya, and Malawi**

**Figure 2.2b. Percentage of men with secondary or higher education in successive surveys in Burkina Faso, Cameroon, Ghana, Kenya, and Malawi**

## ***Occupation***

In SSA, just over half of male respondents in Zimbabwe and Namibia, and 42 percent of men in Comoros, are not currently working and have not worked in the past year (Table 2.2). In Niger and Ethiopia, only 8 percent of interviewed men report that they are not working. Although Gabon has a fairly high proportion of unemployed men (30 percent), it also has the highest proportion in the region of men working in professional, technical, and managerial jobs (16 percent).

In the NAAE region, a large proportion of men are not working in both Kazakhstan and Armenia (40 and 44 percent, respectively), while only 7 percent of men are not working in Turkey. Twenty-three percent of men in Turkey are working at professional, technical, or managerial jobs—at least double the proportion found in Armenia and Kazakhstan.

The countries representing the SSEA region have widely varying levels of unemployment among men. The Philippines has the highest level of unemployment at 20 percent while in Indonesia and Nepal, only 1-2 percent of men report that they are not working and have not worked in the past year. Less than 10 percent of men in the region work in professional, technical, or managerial occupations.

The LAC region overall has relatively low levels of unemployment among men. Haiti is the exception, where 32 percent of men are not working. Haitian men are least likely to have a professional, technical, or managerial job (6 percent), while Bolivian men are most likely (21 percent).

## ***Media Exposure***

In SSA, in all but four countries (Ethiopia, Togo, Mauritania, and Guinea), at least 50 percent of men report that they listen to the radio at least once daily; in Gabon, 90 percent of men listen daily. In NAAE, only about one-third of men in Armenia and Kazakhstan listen to the radio daily. In most countries of SSEA, about half of the men listen daily, the Philippines being the exception (82 percent). Haiti and Brazil have the lowest levels of listenership in the LAC region (about 68 percent), while Bolivia has the highest (90 percent).

Combining information from Table 2.1 on the percentage of men living in urban areas with the data in Table 2.2 on weekly exposure to television indicates that generally, the higher the proportion of men living in urban areas, the higher the levels of television watching are in the country. In SSA, Ethiopia is the country with the smallest proportion of men living in urban areas; it also has the smallest proportion of men who watch television (8 percent). In contrast, the countries of Cameroon, Ghana, and Gabon are all highly urbanized and are among the top five for television watching in their region (49 percent, 66 percent, and 69 percent, respectively). There is also a direct positive correlation between urbanization and television watching in NAAE and SSEA. There is a similar relationship in LAC, where Haiti is the least urbanized country and also has the lowest levels of television viewing (30 percent), and Peru and Brazil are the most urbanized and have the highest levels of television watching (85 percent and 90 percent, respectively).

In SSA, levels of weekly newspaper readership correspond closely to the proportion of literate men: men living in Zimbabwe, Kenya, Namibia, and Gabon are the most likely to read the newspaper (43-57 percent). But literacy is not the only determinant of newspaper readership: in Armenia, where nearly 100 percent of men have attained secondary or higher education, only 30 percent read a newspaper on a weekly basis. Similarly, in Indonesia, where 93 percent of men are literate, less than one-third read the newspaper at least once a week. In the LAC region, Peru shares the distinction with Bolivia of having the highest levels of literacy, with 98 percent of men literate. Even so, 82 percent of men in Peru report having read a newspaper in the past week—24 percentage points higher than any other country in this study.

## *Literacy*

In most countries, literacy is determined during the interview by a short reading test among individuals who have not completed secondary education. In some surveys conducted prior to the introduction of the reading test, respondents were simply asked if they could read a letter or newspaper easily, with difficulty, or not at all. Countries with this type of literacy assessment are marked with a footnote in Table 2.2. Levels of literacy generally follow the same pattern as previously discussed for education: countries in which men have the least education are the most likely to have low levels of literacy.

## **2.3 Gender Attitudes**

Recent inclusion of gender questions in the DHS questionnaires allows researchers to investigate associations between attitudes about gender and selected health and demographic outcomes. The development of these questions was guided by a common understanding of what gender is, how it relates to sex, and how sex and gender together and separately have the potential for affecting population, health, and nutritional outcomes (Kishor, 2005). Typically, questions about gender roles and attitudes are asked only of women. In the more recent surveys, however, men are asked questions about gender-related issues as well.

We take advantage of this opportunity to explore the relationship between men's gender attitudes and population and health outcomes among men, although the subset of countries for which the relevant questions are available is limited. Table 2.3 shows men's attitudes toward women in the SSA, NAAE, SSEA, and LAC regions with regard to household joint purchases, justifications for hitting a wife, and retaliating against a wife who refuses to have sex.

Table 2.3 Gender attitudes of respondents

Percentage of all men who have specific attitudes toward women, Demographic and Health Surveys, 1995-2004

Country	Respondent believes that decisions about large household purchases should be made jointly by husband and wife	Respondent agrees with any of the five specified justifications for hitting a wife <sup>1</sup>	Respondent agrees with a woman's right to refuse sexual intercourse with her husband for all four of the specified reasons <sup>2</sup>	Respondent believes it is justifiable for a husband to retaliate in any of four specified ways if a wife refuses to have sexual intercourse <sup>3</sup>
<b>Sub-Saharan Africa</b>

Nicaragua 1997/98	43.5	na	na	na

Note: Data are for all men except for the following:

Turkey 1998 – Husbands of eligible women

Indonesia 2003 – Currently married men

Nepal 2001 – Ever-married men

<sup>1</sup> Justifications given for a husband to hit his wife are the following: she goes out without telling him, she neglects the children, she argues with him, she refuses to have sex with him, and she burns the food.

<sup>2</sup> Specified reasons that a woman may refuse sexual intercourse with her husband include the following: she knows her husband has a sexually transmitted disease, she knows her husband has sex with women other than his wife/wives, she has recently given birth, or she is tired and not in the mood.

<sup>3</sup> Types of retaliation a husband may justifiably use if his wife refuses to have sexual intercourse with him are the following: get angry and reprimand her, refuse to give her money or other means of financial support, use force and have sex with her even if she does not want to, or go and have sex with other women. In Kazakhstan, only the first of these reasons was included.

na = Not applicable

### ***Joint Decisionmaking about Large Household Purchases***

The first indicator of gender attitude shown in Table 2.3 is the percentage of men who say that final decisions about large household purchases should be made jointly between a husband and his wife/partner. This indicator is intended to reflect the degree to which respondents believe that household economic power should be held by both the husband and the wife rather than exclusively by one or the other.

When comparing across regions the percentage of respondents who say that husbands and wives should have joint final say over large purchases, countries in SSA stand out: in 6 of 11 SSA countries, fewer than 20 percent of men believe that such decisions should be made jointly by husbands and wives. Malawi has the highest proportion of men who believe that purchasing decisions should be made jointly (43 percent), but in Mali and Burkina Faso, only 2-3 percent of men agree with joint decisionmaking on large purchases.

In Armenia, the only country in the NAAE region for which data on this question are available, 57 percent of respondents believe that large purchase decisionmaking should be undertaken jointly between husbands and wives. In three of four SSEA countries, over half of men report that such decisionmaking should be undertaken by both husbands and wives; only in Nepal is the proportion relatively low at 26 percent. In the LAC region, Nicaragua has the lowest proportion of men who think that large purchase decisionmaking should be shared between husbands and wives (44 percent), while Bolivia has the highest proportion (79 percent).

### ***Gender-Role Norms That Justify Men's Control over Women***

Of particular relevance to demographic and health programs is the extent to which women, who are often the targets of such programs, have control over their own behavior, bodies, and sexuality. Accordingly, indicators reflecting men's attitudes towards wife-beating and towards a wife's right to refuse sex with her husband without fear of retaliation allow for the exploration of men's acceptance of norms that subordinate women's bodily integrity and sexuality to men.

#### *Wife-beating*

With regard to the indicator on attitudes about wife-beating, respondents were presented with five hypothetical situations and asked whether a husband was justified in hitting or beating his wife in each situation. The situations included: if she goes out without telling him, if she neglects the children, if she argues with him, if she refuses to have sex with him, and if she burns the food.

A single indicator was created from the responses to each of the five hypothetical situations. If a respondent agreed or said he was not sure whether a husband was justified in beating his wife in any of the five situations, he is counted as justifying wife-beating. Accordingly, the indicator in Table 2.3 reflects the proportion of men in each country who agree with any of the five specified justifications for hitting a wife.

In the SSA region, Malawian men are the least likely to justify hitting a wife (17 percent), while Ethiopian men are the most likely to do so (76 percent). In 10 of the 13 SSA countries with data on this indicator, at least 50 percent of men justify wife-beating. Similarly, just over half of all men in Armenia and Turkey justify wife-beating. Proportions of men who justify wife-beating vary widely in the SSEA region, from 15 percent in Indonesia to 71 percent in Bangladesh. Only 12 percent of Dominican men say that hitting a wife is justified, the lowest proportion of all countries surveyed.

### *Wife's right to refuse sex*

With regard to the indicator on a wife's right to refuse sex, respondents were presented with four hypothetical situations, and for each situation were asked their opinion about whether a wife was justified in refusing sex with her husband. The situations included: if she knows her husband has a sexually transmitted disease, if she knows her husband has sex with other women, if she has recently given birth, and if she is tired or not in the mood.

A single indicator was created from the responses to each of the four hypothetical situations. If a respondent agreed with a wife's right to refuse sex with her husband in all of the four situations, he is counted as agreeing with a wife's right to refuse sex with her husband. Thus, the indicator in Table 2.3 reflects the proportion of men in each country who agree with a wife's right to refuse sex under all specified circumstances.

In 8 of 16 SSA countries with data on this indicator, 50 percent or fewer men agree that a woman has an unqualified right to refuse sex with her husband. Only 21 percent of men in Mali agree with a wife's right to refuse sex, but in Ghana, 66 percent of men agree that a wife can refuse sex with her husband under all of the given circumstances.

As for the remaining countries in which data for this indicator were collected, the percentage of men agreeing with a wife's right to refuse sex range from 59 percent in Armenia to 82 percent in Kazakhstan, with the majority of countries at 70 percent or higher.

### *Justification of retaliation against wives who refuse sex*

For the final indicator in Table 2.3, on justification of retaliation against a wife who has refused sex with her husband, respondents were presented with four retaliatory behaviors and asked their opinion about whether a husband was justified in these behaviors if his wife refused to have sex with him. The types of retaliatory behaviors included were the following: get angry and reprimand her, refuse to give her money or other means of financial support, use force and have sex with her even if she does not want to, or have sex with other women. A single indicator was created from the men's responses to each of the four hypothetical situations. If the respondent justified any of the hypothetical retaliations, he is counted as justifying the use of retaliations against a wife who refuses sex with her husband. Accordingly, the indicator in Table 2.3 reflects the proportion of men in each country who justify a husband's use of retaliatory measures when a wife has refused him sex.

Again, Malawian men are most supportive of women's autonomy and rights: only 25 percent of men thought that retaliation against a wife for refusing sex could be justified. The percentage was similarly low in Ghana (27 percent). In the remaining countries, however, larger proportions of men justify such retaliations, ranging from 36 percent in the Philippines to 64 percent in Zambia and 65 percent in Tanzania.

The fact that significant proportions of men agree with wife-beating and do not recognize a wife's right to refuse sex attests to the socialization of men in traditional gender-role norms giving husbands rights over the behavior and bodies of their wives. It is expected that men with more egalitarian attitudes toward gender might also be more progressive in other behaviors, such as use of contraception, smaller ideal family sizes, and better personal health outcomes.

## **2.4 Wealth Index**

Although DHS surveys do not collect data on consumption or income, they do collect detailed information on dwelling and household characteristics and access to a variety of consumer goods and services that are used as a measure of socioeconomic status. This information has been used to create a composite indicator of long-run household wealth: the wealth index.

The wealth index is a recently developed measure that has been tested in a number of countries in relation to inequities in household income, use of health services, and health outcomes (Gwatkin et al., 2000). It is an indicator of wealth that is consistent with expenditure and income measures (Rutstein, 1999). The wealth index is constructed using the aforementioned household asset and services data and principal components analysis. Each asset is assigned a weight (factor score) generated through principal component analysis, and the resulting asset scores are standardized in relation to a standard normal distribution with a mean of zero and standard deviation of one. Each household is then assigned a score for each asset (one score is given if they have the asset, another is given if they do not), and the scores are summed for each household.

To create wealth quintiles, the de jure population is ranked according to the total score of the household in which they reside, and then classified into five wealth categories, each with the same number of persons. At the national level, approximately 20 percent of the population is in each wealth quintile (thus, no table is shown).

Because household wealth is strongly associated with many population and health outcomes, each subsequent section of this report describes outcomes of interest according to wealth (with the exception of section 6, which provides only univariate statistics).

### **3 Sexual Activity and Contraceptive Use**

Participation in sexual relations is generally a precondition for both childbearing and spread of sexually transmitted infections (STIs), both of which are key components of population growth and reproductive health. Consequently, understanding patterns of sexual behavior and contraceptive use is critical in assessing current needs and implementing programs or policies that encourage healthier choices regarding sex and contraception.

Young people are of particular interest because youth age 15-24 are often making their first decisions about sexual activity and contraception. Accordingly, this section looks at young people separately. It is hoped that by understanding the informational and material needs of young people regarding sex and sexuality, programs can help them make healthy choices that carry into their adult lives. Two direct measures of the level of exposure to the risk of pregnancy and disease are discussed: age at first sexual intercourse and number of partners in the past year.

#### ***Collection of Data on Sexual Activity***

Sexual activity is a key proximate determinant of fertility, and for that reason, DHS and its predecessor, the World Fertility Surveys, have long collected data on the subject. Recently, in an effort to learn more about how sexual activity contributes to the spread of HIV, detailed questions about sexual behavior have been added to the standard DHS questions on sexual activity.

The questionnaire segment on marriage and sexual activity gathers information about current marital status; number of marital or cohabiting partners; whether the respondent has any other regular or occasional partners; age at first sex; current sexual activity; relationship of the respondent to the person with whom he last had sex; length of sexual relationship with the person with whom he last had sex; total number of sexual partners the respondent has had in the past year; and whether the respondent has ever paid for sex. The tables in this section that deal with sexual behavior focus on age of sexual debut and number of sexual partners in the past year. These two variables were selected because of their relevance for family planning and STI prevention programs and because data on these variables are available for all respondents.

#### ***Collection of Data on Contraceptive Knowledge and Use***

When gathering data on contraceptive knowledge, the surveys elicit both respondents' spontaneous knowledge of contraceptive methods and respondents' probed knowledge of contraceptive methods. Interviewers first ask respondents which contraceptive methods they have ever heard of. Then they probe for further knowledge by describing each of the methods not mentioned spontaneously by the respondent and asking if the respondent had ever heard of that method.

The data that are collected are not disaggregated by whether the response was spontaneous or probed; a respondent is classified as knowing a method whether he reported it on his own or after probing. Knowledge of a method simply means that a respondent has heard of it; it does not imply that the respondent approves of the method, knows how it works, knows how to use it, or knows where to obtain it.

Earlier surveys asked men whether they were currently using a contraceptive method with any partner. More recent surveys have changed the question format for asking about contraceptive use because asking about current method use with any partner does not provide sufficient information about when or with whom the method was used. The newer survey question asks men who have had sexual intercourse in the past year whether they used a contraceptive method at their last sexual intercourse, and if so, which method they used. Consequently, the measure derived from these data reflects use of contraception at the time of last sexual intercourse.

Tables in this section are presented separately for never-married men and ever-married men, as well as for all men. The information presented on never-married men pertains largely to young people age 15-19 and 20-24. Because the age of sexual debut in all regions occurs primarily between 15 and 24 years of age, this period is an opportune time to inform youth about the risks associated with sexual activity (Maswanya et al., 1999). Understanding current levels of knowledge among young people about contraceptives and the prevention of STIs, as well as examining the association between knowledge and sexual behavior, may assist policymakers in closing the gap between knowledge and behavior.

Information on men who have ever been married allows for an analysis of men, most of whom are currently married, who are seen as particularly important recipients of program services. Data presented for all men provides a snapshot of the national situation.

### **3.1 Sexual Activity**

Table 3.1a presents the percentage of never-married men who have ever had sex, mean number of partners in the past 12 months among never-married men who have had sex, and median age at sexual debut among never-married men who have had sex, by age group. This table also includes the proportion of men who have ever married, by age group.

In 11 of 25 SSA countries, fully one-third or more of never-married men in the age group 15-19 years have had sexual intercourse. In all of the LAC countries, plus Kazakhstan, at least one-third of never-married 15-19 year olds have had sex. Unmarried youths age 15-19 from Eritrea (3 percent), Mauritania (12 percent), Ethiopia, Armenia, Bangladesh, and the Philippines (all at 13 percent) are the least likely to have had sex during their teenage years. By the time never-married men reach age 25, more than half have had sex in nearly all countries with data, except for the SSEA countries and three countries in SSA (Mauritania, Ethiopia, and Niger). At least three-quarters of never-married men age 25 and over have experienced sexual intercourse in all but six countries (Mauritania, Eritrea, Ethiopia, Niger, Bangladesh, and the Philippines).

Among never-married men age 15-19 who have ever had sex, the mean number of partners in the past year ranges from 0.4 (Niger) to 2.6 (Gabon). A mean number of partners in the past year of less than one indicates that although sexual activity has been initiated, it is infrequent, with many respondents not having sexual relations in the past year. This is the case in eight sub-Saharan African countries (Rwanda, Kenya, Malawi, Uganda, Ghana, Namibia, Mali, and Zambia). A mean number of partners in the past year of greater than one indicates that sexually experienced never-married men age 15-19 had on average more than one partner in the past year. In three countries—Gabon, Brazil, and Peru—never-married men age 15-19 who have ever had sex had, on average, more than two sexual partners in the 12 months prior to the survey. The mean number of partners that never-married respondents report in the year prior to the survey increases directly with increasing age in 10 out of 25 countries.

A mean age at first sex of 15 years is found among the never-married men of Kenya, Gabon, Nicaragua, Haiti, Brazil, and Zambia. The oldest mean age at first sex in any given country is 19 (the Philippines). Waiting until an older age to have sex for the first time tends to reduce fertility, and also serves to reduce exposure to sexually transmitted infections among both men and women.

Table 3.1a Sexual activity, age at first sex, and number of partners in the past 12 months: Never-married men

Percentage of never-married men who have ever had sexual intercourse, and among never-married men who have had sex, mean number of partners in the past 12 months, and among all men, percentage who have ever been married, by age groups, Demographic and Health Surveys, 1995-2004

Note: Figures in parentheses are based on 25-49 unweighted cases, and should be interpreted with caution.

<sup>a</sup> In Comoros, men who did not know where to get a condom were skipped out of the question on the number of partners.

na = Not applicable

The final columns in Table 3.1a show the proportion of all men who have ever been married (and are thus assumed to be sexually experienced). These figures provide information that is complementary to the first three columns in this table regarding sexually active youth age 15-19 and 20-24. Only in Cameroon and Nicaragua do the proportions of men age 15-19 who have married approach or reach 10 percent, while only in Mozambique are over half of men age 20-24 married.

Table 3.1b presents the mean age at first sex among ever-married men and mean number of sexual partners in the past year according to age group and current marital status. In most countries, no mean age at first sex or mean number of partners in the past year is presented for men age 15-19 because

Table 3.1b Age at first sex and number of partners in the past 12 months: Ever-married men who have ever had sex

Note: Data are for all men except for the following:

Turkey 1998 – Husbands of eligible women

Indonesia 2003 – Currently married men; also, data do not indicate if men were married to 1 or 2+ wives

Nepal 2001 – Ever-married men

Note: Figures in parentheses are based on 25-49 unweighted cases and should be interpreted with caution. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

<sup>a</sup> Widowed category was not included in the Cameroon survey<sup>b</sup> In Comoros 1996, "Currently in informal union" and "Widowed" were not included in the "Ever-married" category because they were assigned to the category "Never had sex" (var. MV531). In Comoros, men who did not know where to get a condom were skipped out of the question on number of partners.<sup>c</sup> Means for the number of partners do not include wives.<sup>d</sup> Information is missing on number of partners in 44 cases; they are not included in the denominator.

na = Not applicable

few men of this age have ever been married. Similarly, in most countries, no information can be presented for mean number of partners among widowed men because there are insufficient numbers of widowed men to support statistical analysis.

Among ever-married men age 20-24 in SSA, men in Gabon have the youngest mean age at first sex, at 14.8 years. This is nearly a year younger than all other SSA countries. The region with the lowest mean ages at first sex among ever-married men age 20-24 is LAC, where the greatest mean age at first sex is 16 years in Peru, the Dominican Republic, and Bolivia. The remaining countries in the LAC region have a mean age at first sex of 15 years. The NAAE and SSEA regions have comparatively older ages at first sex among ever-married men age 20-24, ranging from 17 years in Nepal to 20 years in Indonesia.

Among ever-married men currently age 20-24 in SSA, the mean number of sexual partners in the past 12 months is less than two for most countries. However, in Cameroon, Gabon, and Togo, the mean number of partners in the past year is greater than two. In most sub-Saharan African countries, men age 25 and older are similar to younger ever-married men in terms of their average number of partners in the past year.

Among ever-married men in NAAE and SSEA, men age 20-24 as well as men age 25 years and older average one sexual partner for the previous year. Ever-married men in LAC are likely to have had more than one partner in the previous year; men age 20-24 are more likely to have multiple partners than men age 25 and older.

On average, currently-married men have had more than one sexual partner in the past year. Currently-divorced men have had, on average, more partners in the past year than currently-married men.

For informational purposes, Table 3.1c provides survey data on respondents' age at first sex and number of partners in the past 12 months among men who have ever had sex.

Table 3.1c Age at first sex and number of partners in the past 12 months: All men who have ever had sex

Mean age at first sexual intercourse and mean number of partners in the past 12 months, by age group and marital status, Demographic and Health Surveys, 1995-2004

## 3.2 Contraceptive Knowledge and Use

Table 3.2a presents the percentage of never-married men who know specific contraceptive methods. In most countries, 90 percent or more of never-married men had heard of a modern family planning method. In the LAC region, 95 percent or more never-married men have heard of a modern method of contraception. All of the countries where the percentage of men with knowledge of modern contraceptive methods is below 90 percent are located in SSA and include Mauritania (50 percent), Chad (71 percent), and Ethiopia (78 percent), among others.

The condom is the best known method of contraception in all of the four regions. More than half of never-married men in the majority of SSA countries and in all of the LAC countries know about injectables as a contraceptive method; knowledge of this method is much lower among never-married men in Kazakhstan (17 percent) and the Philippines (34 percent), the two countries representing the NAAE and SSEA regions.

In all but three countries, at least 50 percent of never-married men know about the contraceptive pill. Countries where less than 50 percent of never-married men know about the pill include Mauritania, Chad, and Rwanda. A few countries ask about knowledge of emergency contraception. Of these countries, only in Nigeria and Namibia do at least one-quarter of men know about this method.

Table 3.2a Knowledge of contraceptive methods among never-married men

na = Not applicable

Table 3.2b shows that knowledge of any modern contraceptive method is as high among ever-married men as among never-married men. It also shows that ever-married men have higher levels of knowledge about specific methods. At least 70 percent of ever-married men know about the contraceptive pill in nearly all countries. Countries where less than 70 percent of men know about the pill include Chad, Mauritania, Guinea, Nigeria, and Cote d'Ivoire. Ever-married men are also somewhat more likely than never-married men to know about emergency contraception. In four countries where emergency contraception was asked about, more than one-quarter of men know about this method: Namibia and Kenya (28 percent), the Dominican Republic (29 percent), and Nigeria (32 percent).

For informational purposes, Table 3.2c provides data on knowledge of contraceptive methods among all men responding to the survey.

<sup>a</sup> Husband survey

<sup>b</sup> Ever-married men's survey

<sup>c</sup> Currently-married men's survey

Tables 3.3a and 3.3b show the percentage of never-married men and ever-married men, respectively, who know any modern contraceptive method by demographic background characteristics, specifically, age and residence. For both groups of men, knowledge of contraceptive methods increases with age. As expected, urban men have somewhat greater knowledge of contraceptive methods than rural men in nearly all countries. The urban-rural knowledge gap is particularly large in Mauritania, where 65 percent of never-married urban men know a method, but only 25 percent of rural men do; the urban-rural gap is similarly large for ever-married men in Mauritania. Niger, Chad, Ethiopia, Eritrea, and Guinea, among others, also have an urban-rural gap in contraceptive knowledge that exceeds 20 percentage points among never-married men. The gap remains greater than 20 percentage points among ever-married men in Eritrea and Guinea.

A comparison of the data for individuals ages 15-19 and ages 20-24 in Table 3.1a and Table 3.3a shows that in all countries, never-married youths are far more likely to know about modern contraceptive methods (particularly condoms) than they are to engage in sexual activity. This combination of knowledge and behavior suggests that most countries currently have a good foundation for the activities of youth-focused family planning and sexual health programs.

<sup>a</sup> Husband survey

<sup>b</sup> Ever-married men's survey

<sup>c</sup> Currently-married men's survey

na = Not applicable

Table 3.4a shows the percentage of never-married men who know any modern method by socioeconomic background characteristics, specifically, education, occupation, and quintile of the wealth index. Table 3.4b gives the same information for ever-married men. Among both never- and ever-married men, knowledge of a modern method of contraception increases with education in almost all countries. Among ever-married men, 90 percent or more of men with a primary level or higher education know at least one modern contraceptive method in all countries except Bolivia. In general, men who are either not working or who are working in agriculture are less likely to know a modern method than men in other types of employment. Knowledge of contraceptive methods typically increases monotonically with wealth for both never- and ever-married men.

For informational purposes, Table 3.4c provides data from the survey on knowledge of contraceptive methods among all men by socioeconomic background characteristics.

<sup>a</sup> Husband survey

<sup>b</sup> Ever-married men's survey

<sup>c</sup> Currently-married men's survey

Figure 3.1 shows the percentage of ever-married men and never-married men who have ever had sex and report having ever used a modern contraceptive method. Generally, never-married men who have ever had sex are more likely to have ever used a modern contraceptive method than ever-married men. It is likely, though, that different age distributions among the two groups of men result in an exaggeration of any real differences that may exist: married men in the older cohorts were likely already married before family planning programs were available in these countries, while men who have never married are disproportionately likely to fall into the younger cohorts. In many less developed countries, contraceptive use within marriage is still a minority practice. Ever-use of contraception is at least twice as high among never-married men who have had sex than among ever-married men in Mozambique, Guinea, Chad, Nigeria, Mauritania, Senegal, and Niger. Only in the Philippines, Nicaragua, Zimbabwe, Kazakhstan, and Brazil are ever-married men more likely to have ever used a modern contraceptive method than never-married men who have had sex.

**Figure 3.1 Percentage of ever-married men and never-married men who have ever had sex and report ever having used a modern contraceptive method**

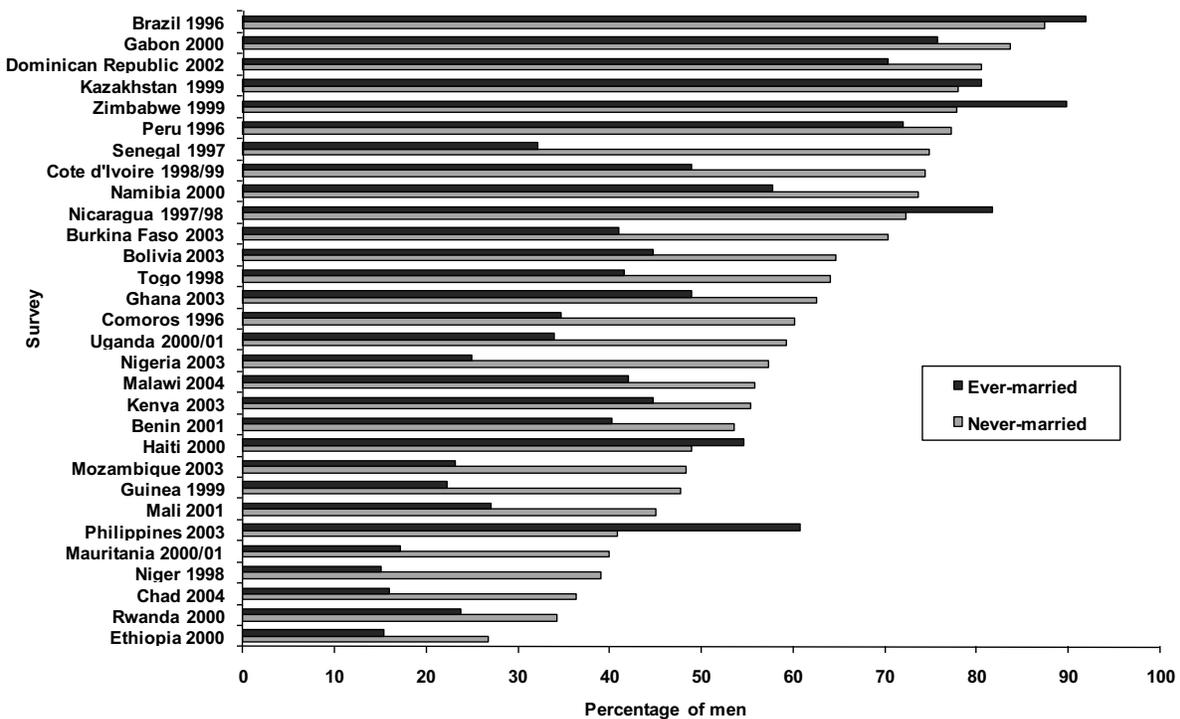

Table 3.5a shows the current or recent use of contraception among never-married men who have ever had sex. Countries with a pound sign notation are those that have implemented the new approach to collecting data on recent contraceptive method use, as discussed above. Table 3.5b reflects the same information for ever-married men.

<sup>a</sup> Husband survey

<sup>b</sup> Ever-married men's survey

<sup>c</sup> Currently-married men's survey

<sup>#</sup> In these countries, the questions on contraceptive use were asked for most recent use only, which is in the past 12 months instead of in the current time.

na = Not applicable

In the SSA region, never-married men are most likely to be currently or recently using a modern contraceptive method in Senegal, Burkina Faso, and Namibia (58 percent in each country); they are least likely to be using a modern method in Mauritania (16 percent), Rwanda (21 percent), and Chad (23 percent). Among ever-married men in the SSA region, men in Zambia (31 percent), Namibia (45 percent), and Zimbabwe (59 percent) are the most likely to be using a modern method, while men in Rwanda (5 percent), Chad (6 percent), and Mauritania (7 percent) are the least likely. In the LAC region, never-married men's usage of a modern contraceptive method ranges from 25-26 percent in Nicaragua and Haiti to 54 percent in the Dominican Republic. Ever-married men's usage in LAC is somewhat higher, ranging from 27 percent in Haiti to 69 percent in Brazil.

Condoms are overwhelmingly the method of choice among never-married men in all regions, nearly to the exclusion of other methods. Seventeen countries have a condom usage prevalence of 33 percent or higher, and as many as 55 percent of sexually active never-married men in Namibia, Burkina Faso, and Senegal report current/recent use of condoms. Never-married men in LAC countries report some pill use, with Brazil having the highest prevalence of pill use at 12 percent.

Though condom prevalence is not as high among ever-married men in SSA as never-married men, ever-married men are still more likely to use condoms than any other method. Eighteen countries in SSA have at least 5 percent condom prevalence. Namibia, Gabon, and Tanzania have the highest prevalence of current/recent condom usage, at 19 percent, 21 percent, and 22 percent, respectively. The next most frequently reported method in SSA, the contraceptive pill, has a prevalence of 5 percent or greater in eight countries. Forty-two percent of men in Zimbabwe report using the pill for their most recent contraception use. Zambia has the second-highest prevalence of pill usage at 11 percent.

Current/recent condom use among ever-married men in LAC ranges from 4 percent in Nicaragua to 10 percent in the Dominican Republic. Pill use is more popular in LAC, ranging from 3 percent in Bolivia to 20 percent in Brazil. For informational purposes, Table 3.5c provides data on current use of specific contraceptive methods among all men who were surveyed.

<sup>a</sup> Husband survey

<sup>b</sup> Ever-married men's survey

<sup>c</sup> Currently-married men's survey

<sup>#</sup> In these countries, the questions on contraceptive use were asked for most recent use only, which is in the past 12 months instead of in the current time.

na = Not applicable

Table 3.6a shows the percentage of never-married men who have ever had sex who are currently using a modern contraceptive method by age and residence. Table 3.6b shows these data for ever-married men. In most countries, current/recent use of a modern contraceptive method increases with age among never-married men. Among ever-married men, the relationship between age and contraceptive use is either flat or has a slight inverted U shape. For both never-married and ever-married men, there is a large gap between the proportion of urban men and rural men who are currently using a contraceptive method; the gap is largest among countries in the SSA region.

Table 3.6a Current use of a modern contraceptive method among never-married men by demographic background characteristics

Percentage of never-married men who are currently using a modern method by age and residence, Demographic and Health Surveys, 1995-2004

<sup>a</sup> Husband survey

<sup>b</sup> Ever-married men's survey

<sup>c</sup> Currently-married men's survey

<sup>#</sup> In these countries, the questions on contraceptive use were asked for most recent use only, which is in the past 12 months instead of in the current time.

na = Not applicable

Table 3.7a shows the percentage of never-married men who have ever had sex and are currently using a modern method by socioeconomic characteristics, specifically, education, occupation, wealth index, and media exposure; Table 3.7b shows these data for ever-married men.

As expected, the proportion of men using contraception increases directly with education and wealth among both never- and ever-married men in nearly all countries. Among ever-married men in most countries, those who are in professional, technical, and managerial occupations are more likely to report current or recent contraceptive use than men in other occupations. Among never-married men, however, the relationship between these occupations and contraceptive use is not as clear, in part because is that never-married men are disproportionately young and many have therefore not yet had the opportunity to reach the professional, technical, or managerial ranks. For both never- and ever-married men in most countries, those in agricultural occupations and those not working are the least likely to use a contraceptive method.

For informational purposes, Table 3.7c provides data from the survey on the percentage of all men currently using a modern contraceptive method by sociodemographic background characteristics.

Table 3.7a Current use of a modern contraceptive method among never-married men who have ever had sex by socioeconomic background characteristics

<sup>a</sup> Husband survey

<sup>b</sup> Ever-married men's survey

<sup>c</sup> Currently-married men's survey

<sup>d</sup> In these countries, respondents were asked about daily, rather than weekly, radio listenership.

<sup>#</sup> In these countries, the questions on contraceptive use were asked for most recent use only, which is in the past 12 months instead of in the current time.

Figures 3.2a through 3.2d, which show the percentage of all men who are currently using a modern contraceptive method according to gender attitudes, demonstrate the consistency with which men's reported contraceptive use is associated with men's progressive gender attitudes.

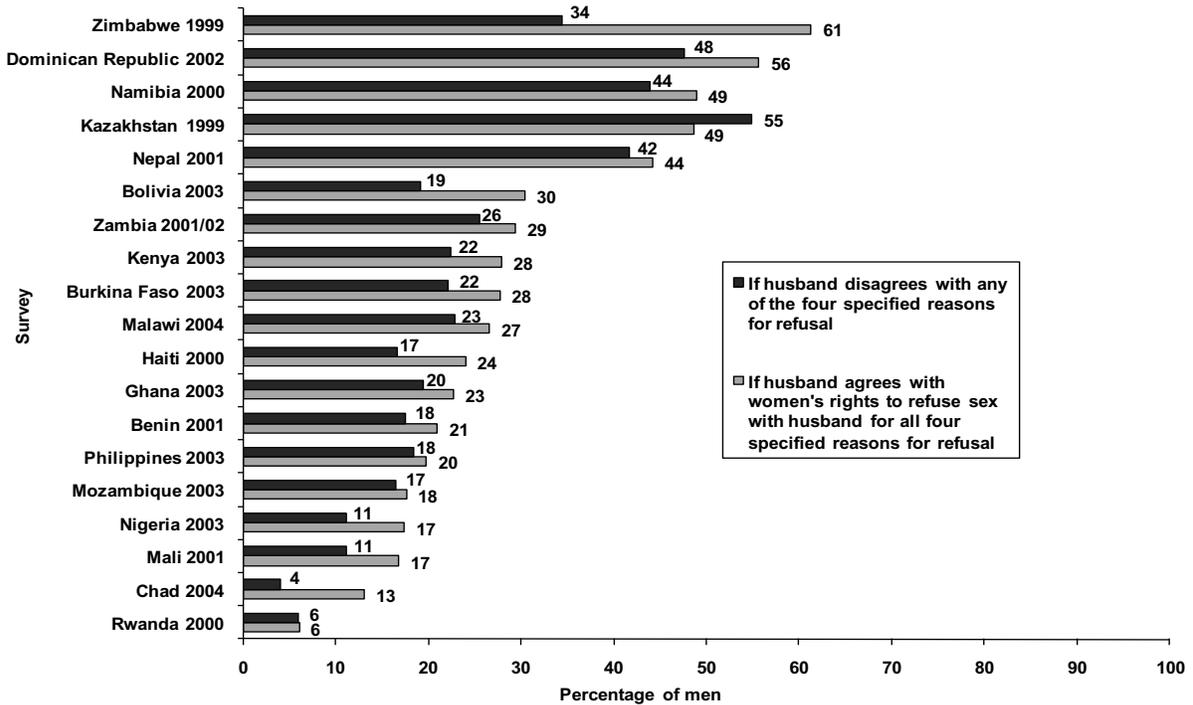

**Figure 3.2a Percentage of men using a contraceptive method according to gender attitudes: Joint decisionmaking about large household purchases**

**Figure 3.2b Percentage of men using a contraceptive method according to gender attitudes: Justifications for hitting one's wife**

**Figure 3.2c Percentage of men using a contraceptive method according to gender attitudes: Agreement with wife's right to refuse sex**

**Figure 3.2d Percentage of men using a contraceptive method according to gender attitudes: Views about whether retaliation is justified if wife refuses sex**

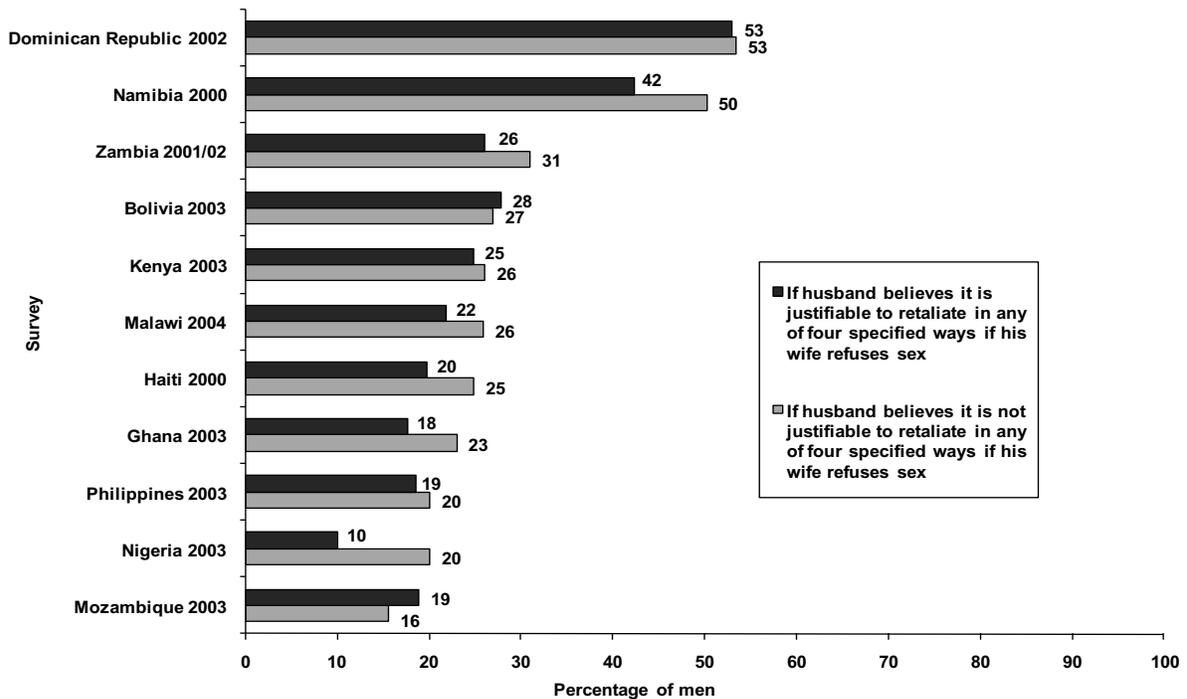

Figure 3.2a compares contraceptive use between men who say husbands should make decisions about large household purchases jointly with their wives and men who say otherwise. In nearly every country, men who believe decisions about large household purchases should be made jointly with their wives are more likely than other men to say that they are currently using or have recently used contraception.

Similarly, in Figure 3.2b, men who agree with none of the specified reasons for hitting a wife are more likely to report using contraception than men who agree with any reason for hitting a wife. Figure 3.2c shows that men who agree with a woman's right to refuse sex are more likely to be using contraception than men who say that there are circumstances under which a wife has no right to refuse sex with her husband.

Finally, Figure 3.2d demonstrates that in most countries, men who do not think it is justifiable to retaliate against a wife who has refused to have sex with her husband are more likely to be using contraception than men who find it justifiable to retaliate against a wife who refuses sex.

Because data regarding the knowledge of family planning methods were collected in the same manner for men and women, they can be compared by gender within countries. Table 3.8 compares currently-married men's and women's knowledge of modern, traditional, and any contraception. Overall, levels of knowledge of modern contraception are very high, with knowledge exceeding 90 percent in most countries.

In 18 of the 26 SSA countries shown in the table, men's and women's knowledge levels with regard to modern contraception are within 5 percentage points of one another. In Mauritania, women are much more likely to know a modern method of contraception than men (68 percent as compared to 55 percent, respectively), but Mauritania is the exception. In Mali, Nigeria, Eritrea, Niger, and Chad, men are considerably more likely to know a modern method of contraception than women are. In Chad, three-quarters of men know a modern method, whereas only about half of women do. Differences in knowledge of modern contraception are slight in the other global regions, as well, with men and women within 2 percentage points of one another in most countries.

National-level comparisons between men and women in the usage of modern methods cannot be made. In some surveys, variations in the questionnaire result in men reporting exclusively on methods that they themselves use, rather than allowing men to also report the use of woman-controlled methods for the contraceptive benefit of both partners. The figures would thus not be comparable.

<sup>a</sup> Husband survey<sup>b</sup> Ever-married men's survey<sup>c</sup> Currently-married men's survey

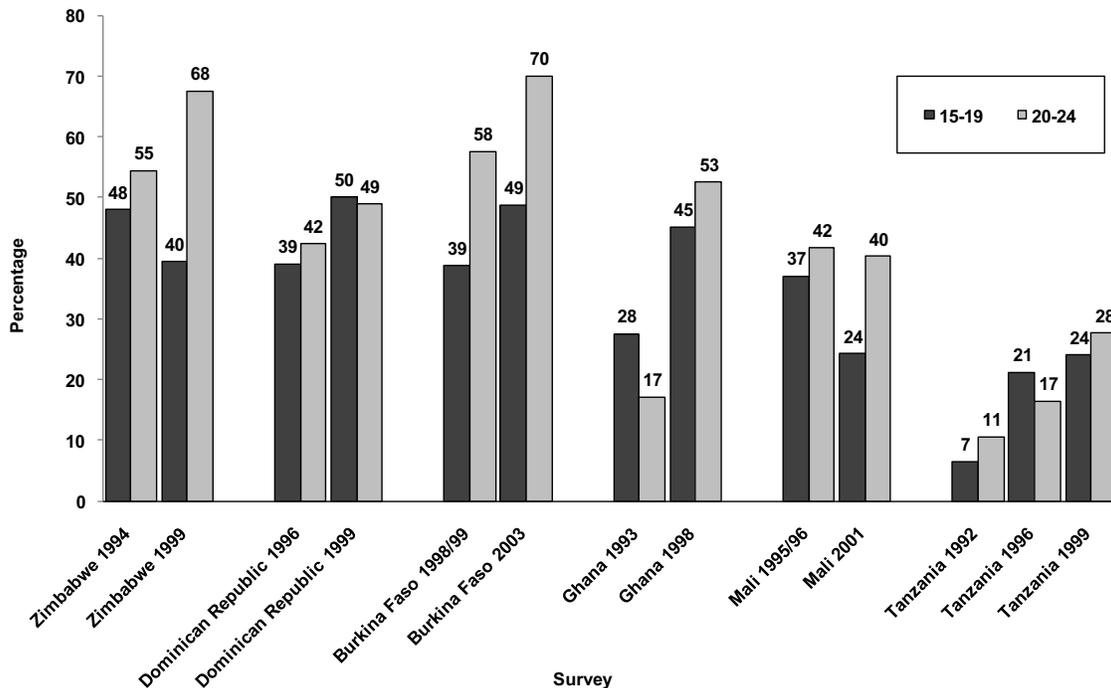

na = Not applicable

Figures 3.3a through 3.3c show trends in indicators of sexual activity and contraceptive use for countries that have had at least two men's surveys. Figure 3.3a reflects trends in condom use among sexually active unmarried men in age groups 15-19 and 20-24. The data indicate that there is an increase in condom use over time. Notable exceptions to the general findings presented here include Zimbabwe, where condom use among individuals age 15-19 decreases over time, and Mali, where condom use in both age groups decreases over time. The figure also shows that levels of current condom use among men age 20-24 are higher than among men age 15-19, with the exception of the Dominican Republic 1999, and Ghana 1993.

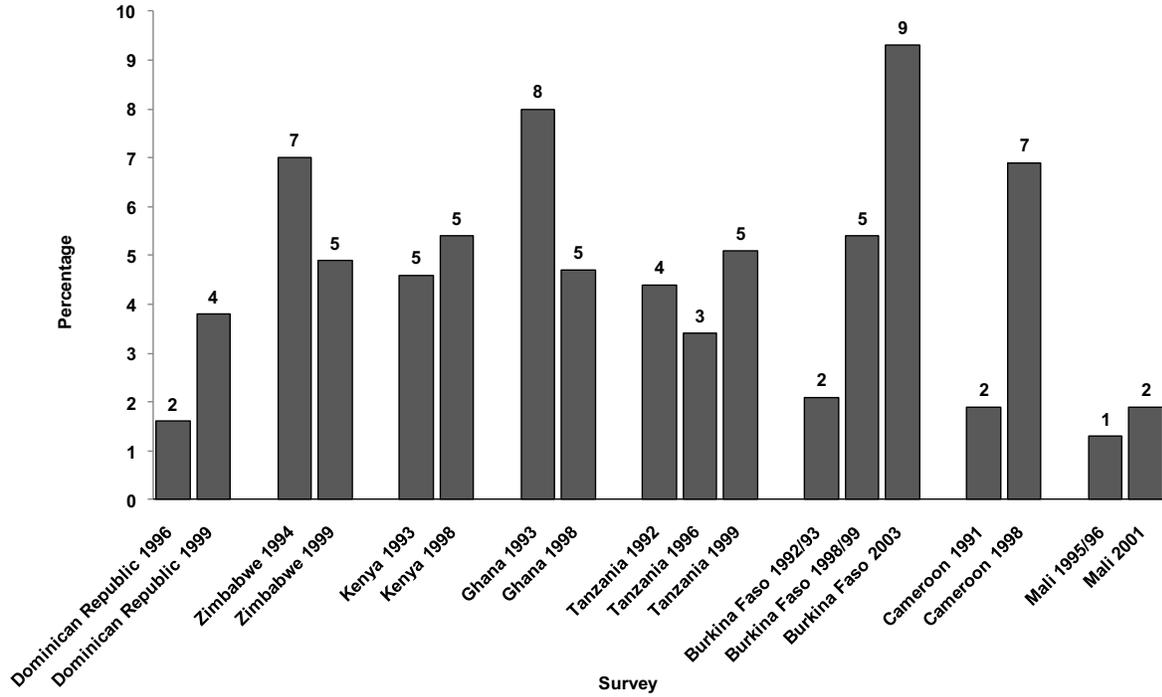

Figure 3.3b shows trends in contraceptive use among men with four or more children. Overall, contraceptive use is low among these men. In all countries, use of contraceptives is stable or increases over time for this group of men, with the exception of Zimbabwe and Ghana. The biggest proportional increase in method use among these men was in Cameroon, with a greater than 250 percent increase in usage between the first and second surveys. Burkina Faso also had a large proportional increase of 72 percent between 1998/99 and 2003.

Figure 3.3c shows trends in median age at first sex among men age 25-54. The data show that in most countries, there has been an incremental increase in the median age at first sex. Only two countries, Mali and Bolivia, register a slight decrease in median age at first sex.

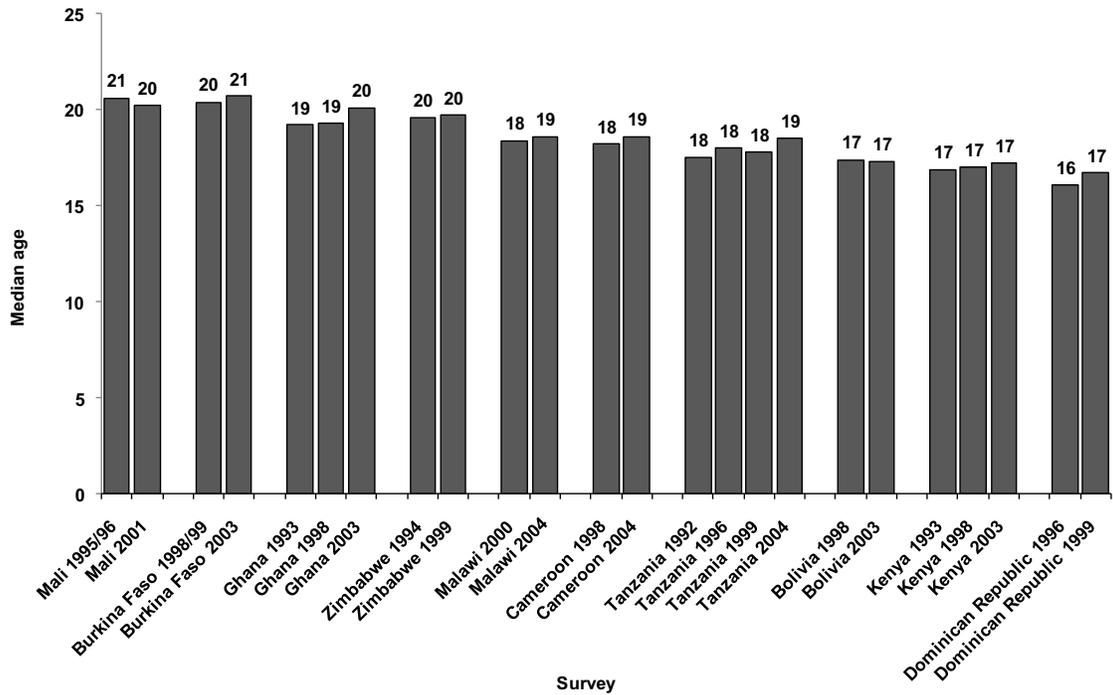

**Figure 3.3a Trends in condom use among sexually active unmarried men age 15-19 and 20-24**

**Figure 3.3b Trends in percentage of men who have four or more children who are currently using condoms**

## 4 Men's Fertility and Preferences

Although women bear and birth children, and are usually their primary caregivers, fatherhood also has implications for men's lives, particularly in terms of providing financial and social support for children. Husbands often play an important role in decisionmaking regarding the timing and number of a couple's births (Bankole and Singh, 1998). To better understand the factors associated with fatherhood in the countries examined here, this section examines men's current fertility and their preferences for future fertility according to their background characteristics.

### 4.1 Fertility

Table 4.1 shows the percentage distribution of ever-married men by three fertility-related variables: 1) the number of children ever born; 2) the percentage among men with more than one child whose children have been borne by more than one woman; and 3) the total fertility rate (TFR). The TFR, an indicator of fertility based on data from female respondents to the DHS, is given in this table as a reference point for the men's fertility-related data. The TFR is defined as the total number of births a woman would have by the end of her childbearing period if she were to pass through those years bearing children at the currently observed rates of age-specific fertility (age-specific fertility is the number of births per thousand women in the specified age group).

Sub-Saharan Africa has the highest fertility levels of all four regions represented in this report, ranging from a low of 4.0 (Zimbabwe) to a high of 7.2 (Niger). Of the 26 SSA countries represented here, 19 have TFRs of 5.0 or higher. Proportions of men with no children range from 5 percent in Uganda to 17 percent in Cameroon, while the proportion with 5 or more children ranges from 20 percent in Tanzania to just over half of men in Uganda and Niger.

The NAAE countries have the lowest fertility levels of all four regions, with two of the three countries showing below-replacement fertility (Armenia, TFR: 1.7; Kazakhstan, TFR: 2.0). The percentage of men with no children ranges from 7 percent in Armenia to 9 percent in Turkey. Compared to the number in SSA, few men in the NAAE region have fathered 5 or more children: 4 percent in Armenia, 9 percent in Kazakhstan, and 19 percent in Turkey.

Total fertility rates in the SSEA region range from 2.6 in Indonesia to 4.1 in Nepal. The percentage of men with no children in this region ranges from 9 percent in Indonesia to 11 percent in the Philippines, while proportions of men with 5 or more children range from 15-25 percent in the region.

In the LAC region, the TFR ranges from 2.5 in Brazil to 4.7 in Haiti. The percentage of men in this region with no children ranges from 7 percent in Bolivia to 13 percent in the Dominican Republic; the percentage of men with 5 or more children ranges from 16 percent in Brazil to 38 percent in Haiti.

A few countries, mostly within the SSA region, collected information about the number of women with whom the respondent has had children. The percentages of men with children by 2 or more women is shown in Table 4.1. The denominator for these figures is the total number of men who have two or more children. Of the SSA countries that asked for this information, one-quarter (Rwanda) to one-half (Uganda) of men reported that their children had been borne by two or more women. In contrast, only 6 percent of Filipino men reported that they have had children by 2 or more women. In the LAC region, between 18 percent and 50 percent (Bolivia and Haiti, respectively) of men have had children by two or more women. There is no direct association at the national level between the proportion of men who have fathered children with more than one woman and levels of fertility.

Table 4.1 Men's fertility

Percentage of ever-married men by number of children ever born; among all men with more than one child, the percentage of men by number of mothers to respondent's children; and women's total fertility rate, Demographic and Health Surveys, 1995-2004

Country	Number of children ever born				Total	Number of men	Among all men with more than one child, number of mothers to respondent's children		Total	Number of men	TFR

<sup>a</sup> Husband survey

<sup>b</sup> Ever-married men's survey

<sup>c</sup> Currently-married men's survey

\* In this country, the questions were asked about the number of living children but not the number of children ever born.

na = Not applicable

## 4.2 Ideal Family Size

Ideal family size marks the boundaries of socially acceptable reproductive behavior (Westoff, 1991). Changes over time in ideal family size may indicate shifts in attitude that precede changes in behavior. Yet ideal family size is of limited utility in predicting actual behavior (Bongaarts, 1990; Pritchett, 1994).

Men are asked two questions to determine ideal family size. Respondents with no living children were asked, “If you could choose exactly the number of children to have in your lifetime, how many would that be?” For respondents who had living children, the question was phrased as follows: “If you could go back to the time when you did not have any children and could choose exactly the number of children to have in your lifetime, how many would that be?”

Table 4.2 shows the mean ideal number of children among all men by demographic background characteristics, specifically, age, residence, and marital status. It also shows the mean ideal number of children among all women as a point of comparison.

When discussing the concept of ideal number of children in a cross-national comparison, it is important to note the differences in proportions of men who give nonnumeric answers (such as “it is up to God”) to the questions about ideal family size (also shown in Table 4.2). The data on ideal family size in countries where large proportions of respondents give nonnumeric answers are not strictly comparable to those countries where relatively few men give nonnumeric answers. The mean ideal family size may be downward-biased in countries with higher proportions of respondents giving nonnumeric responses, given the probable religiosity of respondents who give such nonnumeric responses and the demonstrated association between religiosity and higher ideal family sizes.

Sub-Saharan African countries with large Muslim populations have the highest levels of nonnumeric responses to questions about ideal family size. Niger, Mali, Senegal, and Mauritania all report more than 20 percent of men with a nonnumeric response to this question. Kazakhstan is the only other country outside of sub-Saharan Africa with similar levels of nonnumeric responses (24 percent). Within the SSEA region, Indonesia has the highest level of nonnumeric responses, at a moderate 9 percent. Proportions of nonnumeric responses are quite low in the remaining SSEA countries, and all of the LAC countries.

In SSA, there is a direct relationship of ideal family size to age: the oldest age groups have the highest ideal family sizes, and these ideals decrease with decreasing age. Respondents age 15-19 at the time of the survey generally report the same ideal family size, or a slightly higher mean number of children they would like to have, than respondents age 20-24 at the time of the survey. This observation may indicate the beginning of a reversal of the previous downward trend in ideal family size. A 2006 study on Kenya by Westoff and Cross discusses this phenomenon in detail (Westoff and Cross, 2006).

For the two countries in the NAAE region for which there are data, men’s mean ideal number of children is almost the same across the age cohorts 15-19, 20-24, and 25-29; in Turkey, it is the same from age 15 through age 49. This suggests that the ideational fertility transition may have bottomed out in Turkey at an ideal family size of about 2.6 children. In SSEA, similar ideals about family sizes are held across several age groups, and in several countries: men ages 15-29 in Bangladesh, Nepal, and Indonesia all agree that having 2.2-2.6 children is ideal. In the Philippines, ideal family size seems to have plateaued among the younger cohorts at about 3.2 children. Similarly, in the LAC region, family size preferences in the Dominican Republic and Haiti seem to have stabilized at about 3.3 children, while the mean ideal number is about 1 child lower in the remaining LAC countries.

Not surprisingly, mean ideal family size is larger in rural areas than urban. The countries with the biggest differences in mean ideal family size between urban and rural areas tend to be SSA countries with a significant agricultural sector and a significant Muslim population. In Senegal and Nigeria, rural men want 3.1 children more than urban men. In Chad and Benin, rural men want 3.4 children more than urban men. Rural men in Niger have an ideal family size that is nearly 5 children greater than their urban counterparts.

Table 4.2. Ideal number of children for all men by demographic background characteristics

Men's mean ideal number of children by age, residence, and marital status; and ideal number of children among all women, Demographic and Health Surveys, 1995-2004

<sup>a</sup> Husband survey

<sup>b</sup> Ever-married men's survey

<sup>c</sup> Currently-married men's survey; the data do not reflect whether the respondent is married to 1 or 2+ wives.

na = Not applicable

Regarding the association between marital union and ideal family size, it is not surprising that the unmarried tend to have the smallest ideal family size; they also tend to be the youngest men in the sample, and younger men tend to have smaller family size preferences. It also is not surprising that men with two wives tend to have larger ideal family sizes than men with one wife. In Ethiopia, men with two wives have a mean ideal family size that is 9 children larger than men with one wife; in Nigeria, the difference is 8 children. In SSA, men living in informal unions tend to have a slightly smaller ideal family size than men in a formal marital union with one wife. In the LAC region, however, preferences do not vary by formal status of union, perhaps reflecting the accepted nature of informal unions in that part of the world. In most SSA countries, divorced men have slightly smaller ideal family sizes than men who are currently married to one wife. In LAC, divorced men have slightly larger ideal family sizes than currently-married men.

In all countries outside of SSA, the difference between men's and women's mean preferred family size is 0.5 children or less, indicating that men and women generally agree about the desired number of children. In the SSA region, however, the difference between men's and women's mean ideal family sizes is frequently larger than 0.5 children. In some cases, the difference is much larger: in 10 SSA countries, the difference between men's and women's ideal is 1 child or more, with men, on average, wanting more children than women. In Niger, men want 2.5 more children than women. In Chad, men want 2.9 more children and men in Benin want 3.0 more children than women. It is notable that in all but three countries, men want more children than women.

Table 4.3 shows men's mean ideal number of children by socioeconomic background characteristics (education, employment, and wealth index), as well as ideal number of children among all women. In every country except Kazakhstan, the mean ideal number of children decreases with increasing education. Ideal family size in Kazakhstan remains at a constant of 3.2 children among men who have completed primary school and those who have a secondary education.

The difference in mean ideal family size between educational categories can be quite large. In most SSA countries, differences from one level of education to the next are at least 1 child. In 11 countries, there is at least a 2-child difference in ideal family size between those with no education and those with primary education. In six countries (Benin, Chad, Mali, Mozambique, Niger, and Nigeria), there is a difference of at least 2 children between the ideal family size of those with primary education and that of those with secondary education.

In every country except Turkey, men who work in agricultural occupations have larger ideal family sizes than men in other occupations. In over half (22) of all countries, men who report that they are not working have the smallest ideal family sizes; in 13 countries, men who are working in professional, technical, or managerial jobs have the smallest ideal family sizes.

In all countries, men in the wealthiest quintile have smaller ideal family sizes than men in the poorest quintile. There is generally a negative and monotonic relationship between wealth and desire for many children, but the gradient of that relationship is not the same across all countries. In some places, such as Mauritania, Bolivia, and the Dominican Republic, the ratio of the poorest quintile to the wealthiest is 1.1, while in other places, such as Nigeria and Côte d'Ivoire, the ratio is 2.2, meaning that ideal family size is twice as large in the poorest quintile as it is in the wealthiest.

Table 4.4 shows men's ideal number of children according to their gender attitudes. Although differences, where they exist, are very small between men who are and who are not supportive of women's right to participate in household decisionmaking, to refuse sex, and to be free from violence from their husbands, the differences are fairly consistent in direction. In most cases, men who have more progressive attitudes towards women are more likely to have slightly smaller ideal family sizes than men who do not have progressive attitudes towards women.

Table 4.4 Ideal number of children for all men by gender attitudes

Men's mean ideal number of children by gender attitudes, Demographic and Health Surveys, 1995-2004

Country	Decisionmaking about large purchases		Justification for hitting wife <sup>1</sup>		Wife's right to refuse sex <sup>2</sup>		Retaliation against wife for refusing sex <sup>3</sup>	
	Decisions about large household purchases should be made jointly between husband and wife	Decisions about large household purchases should not be made jointly between husband and wife	If respondent agrees with none of the five specified justifications for hitting a wife	If respondent agrees with any of the five specified justifications for hitting a wife <sup>1</sup>	If respondent agrees with women's rights to refuse sex with her husband for all four specified reasons for refusal	If respondent disagrees with any of the four specified reasons for refusal	If respondent believes it is not justifiable for a husband to retaliate in any of four specified ways if a wife refuses sex	If respondent believes it is justifiable for a husband to retaliate in any of four specified ways if a wife refuses sex

<sup>1</sup> Justifications given for a husband to hit his wife are as follows: If she goes out without telling him, if she neglects the children, if she argues with him, if she refuses to have sex with him, and if she burns the food.

<sup>2</sup> Specified reasons that a woman may refuse sex include the following: She knows her husband has a sexually-transmitted disease, she knows her husband has sex with women other than his wife/wives, she has recently given birth, or she is tired and not in the mood.

<sup>3</sup> Types of retaliations a husband may justify for his wife refusing to have sex are as follows: Get angry and reprimand her, refuse to give her money or other means of financial support, use force and have sex with her even if she does not want to, or go and have sex with other women.

( ) indicates that figure should be interpreted with caution: N = 25-49.

<sup>c</sup> Currently-married men's survey

na = Not applicable

### 4.3 Fertility Preferences

Table 4.5 shows the percentage of currently-married men and women who want no more children, by number of surviving children. Countries with higher proportions of men and women wishing to remain childless also are more likely to have relatively higher proportions of men and women who want to limit their family size after 1 or 2 children.

In SSA, it is rare for a man who has no children of his own to declare that he wants no children. In 6 countries, no childless men say that they never want to have children; in 19 of 24 SSA countries with data on this topic, less than 5 percent say that they would prefer to remain childless. Only in Comoros and Namibia do greater than 10 percent of men state that they wish to remain childless (12 percent and 16 percent, respectively). Similarly, it is rare for childless women in SSA to say that they want no children, although often women are more likely to wish to remain childless than men. Namibia stands out in this regard: 24 percent of childless women in Namibia say that they wish to remain childless. In every country at least some childless women wish to remain childless.

In the LAC region, it is much more common than in the SSA region for both childless men and childless women to say that they prefer to remain childless. In five out of six LAC countries, at least 10 percent of men prefer to remain childless; as many as 21 percent of Brazilian men feel this way. Only in Haiti does the proportion of men wishing to remain childless resemble African preferences, with 1 percent of men stating that they want no children. In four out of six LAC countries, more than 10 percent of childless women wish to remain childless. In Haiti and Bolivia, larger proportions of women than men wish to remain childless.

In the five NAAE and SSEA countries for which data are available, four countries have between 3 percent and 7 percent of men who are childless and wish to remain so. Only in Nepal, which is an ever-married men's survey, does a large proportion of men with no children say that they do not want children in the future.

Once men have had 1-2 children, the proportion wanting no more children increases to at least one-third in all regions outside of SSA, with the exception of Haiti, where just over a quarter of men with 1-2 living children state that they want no more children. In SSA, only Namibia, with 35 percent of men with 1-2 children reporting that they want no more, reaches similar levels of desired childlessness. Eighteen percent of men in Malawi, Zimbabwe, and Kenya report the same; the figure is 15 percent among Gabonese men. In more than half of SSA countries, only after having had 5 or more children do at least one-third of men report that they do not want any more children.

In nearly every country, the proportion of women with 1-2 children who want no more is greater than the corresponding proportion for men. The proportion of women who have 3-4 children and say that they want no more is at least 15 percentage points higher than the corresponding proportion of men in several countries: Mozambique and the Philippines (15 points); Ethiopia, the Dominican Republic, and Haiti (16 points); Kazakhstan and Nicaragua (17 points); and Uganda (19 points), Namibia (20 points), and Nepal (23 points). This points to a considerable disagreement regarding fertility desires between men and women in these countries.

## 5 Men's Health

Men's participation in matters of reproductive health is not the only important if neglected area of investigation. Indicators of men's general health typically are overlooked as well. This section presents data on men's smoking and drinking behaviors as indicators of influences on men's health, as well as data on men's experience of symptoms of sexually transmitted infections (STIs).

### 5.1 Smoking

According to the World Health Organization, tobacco is the second major cause of death in the world and is the fourth most common risk factor for disease worldwide (World Health Organization, 2007). Tobacco use is a major cause of avoidable illness and premature death. Poverty and tobacco use are also linked (World Health Organization, 2004b), as illness caused by tobacco use contributes to lost productivity and higher health care expenditure. Money spent on tobacco also takes away from money that could be spent to fulfill the needs of the household. The adverse health effects caused by tobacco use further stress already burdened health care systems, especially in developing countries.

In the DHS, respondents are asked if they smoke cigarettes or tobacco; if they respond in the affirmative, they are included in the analysis as smokers. Chewing tobacco is not included in this report, although some surveys do ask about it.

Table 5.1 shows the percentage of men who smoke by demographic background characteristics, namely, age, residence, and marital status. In SSA, the lowest percentages of men who smoke are in Ghana and Nigeria (10 percent), while the highest percentage of smokers is in Namibia (28 percent). In general, about a quarter of men in the SSA region use tobacco.

In the SSEA region, Nepal has the highest percentage of male smokers, 72 percent. The percentage of male smokers in the Philippines and Bangladesh falls between 55 percent and 60 percent. Sixty-eight percent of Armenian men smoke, but only about 15 percent of men in the LAC countries of Haiti and the Dominican Republic smoke.

Table 5.1 Men's health behaviors by demographic background characteristics: smoking

\* Figure suppressed since N < 25.

<sup>b</sup> ( ) indicates that figure should be interpreted with caution: N = 25-29.  
<sup>c</sup> Ever-married men's survey

Figure 5.1 shows that the percentage of men who smoke generally increases with age across all four regions considered in this report. In Armenia, the percentage of men who smoke increases by 52 percentage points between the 15-19 age group (20 percent) and the 20-24 age group (72 percent). Men in the 15-19 age group are the least likely to smoke in all countries, and Nepal has the highest percentage of men in this age group who smoke (37 percent). The use of tobacco during adolescence is a predictor of future use, so it is important to target smoking prevention programs to this age group (Kotwal, Thakur, and Seth, 2005).

**Figure 5.1 Percentage of men who smoke, by age group**

With few exceptions, smoking is more common in rural than in urban areas. The exceptions are Namibia, Armenia, Bangladesh, and the Dominican Republic. In all countries, never-married men are less likely to smoke than ever-married men. This may be the case again because never-married men tend to be younger than married men. In all sub-Saharan countries, the percentage of men who smoke is higher among men who are divorced or separated compared with those who are married with one wife.

Table 5.2 shows the percentage of men who smoke by socioeconomic background characteristics, specifically, education, occupation, and wealth index quintile. In all countries except for Namibia and Nigeria, the percentage of men who smoke decreases as level of education increases. This could indicate better knowledge of the dangers of tobacco use among more educated men. In Namibia, the percentage decreases with education up to the primary level, but then slightly increases among men with a secondary or higher education. The opposite is true in Nigeria, where the percentage increases up to the primary level, then decreases among men with a secondary or higher education.

In all countries except Nepal, the percentage of men who smoke is lowest among men who are not working. This may be because they have less disposable income than working men have, or because they are younger. In general, the next lowest percentage of men who smoke occurs among those who work in professional occupations. One possible explanation is that these men are likely to be more educated; as previously described, the percentage of male smokers decreases as education level increases. In all regions except SSA, men who work in agriculture smoke more than men who work in other occupations. In general, the percentage of smokers decreases with increasing level of wealth.

## 5.2 Alcohol Consumption

Alcohol consumption has significant health and social consequences. Every year, approximately 1.8 million people worldwide die from alcohol use. Intoxication, alcohol dependence, and other biochemical effects of alcohol can damage the body. Road traffic accidents, falls, fires, and other unintentional injuries have also been associated with the use of alcohol. Alcohol is strongly associated with crime and domestic violence. Heavy drinking can take a toll on family relationships, and can also cause problems in the workplace and contribute to interpersonal violence. The purchase of alcohol by individuals living in impoverished conditions only contributes further to their poor economic situation because it diverts scarce resources from their families and households (World Health Organization, 2004a). Yet there are some health benefits associated with the moderate consumption of some kinds of alcoholic beverages, unlike smoking (Byles et al., 2006).

Table 5.3 shows the percentage of men who drink alcohol by age, residence, and marital status. Countries ask slightly differing questions about alcohol consumption, contributing to the variation in the data presented in this table. In particular, in Malawi, men were asked about how frequently they get drunk, while most other countries ask whether the respondent consumed any alcohol during the reference period. Most countries use a period of the past 30 days as a reference, while countries such as Burkina Faso, Mozambique, the Philippines, and Haiti assess drinking over the previous three months, and Nepal asked about drinking in the past seven days. The data thus for the most part reflect whether the respondent consumed alcohol in the given time period, not how much alcohol was consumed. When comparing across countries, it is important to remember that the data are not strictly comparable for those countries where a country specific reference period was used when asking questions about alcohol consumption.

Consistent across nearly all countries, the lowest percentage of men who drink can be found in the 15-19 age group. Alcohol can be less accessible at this age, and youth may have less money to spend compared to adult men. The highest percentage of youngest drinkers can be found in the Dominican Republic, where 65 percent of men between the ages of 15 and 19 report having consumed alcohol in the past 30 days. In four out of sixteen countries (Mozambique, Rwanda, Zimbabwe, and Armenia), the percentage of men who drink increases monotonically with age.

Proportions of men who consume alcohol vary widely across cultures. Within the SSA region, in Nigeria, 25 percent of men report having consumed alcohol in the past 30 days, while in Zambia, 45 percent of men report the same. Fifty-four percent of Rwandan men report having consumed alcohol in the past 3 months. The country with the highest proportion of reported alcohol consumption in the past 30 days is the Dominican Republic (73 percent). Eighty percent of respondents from Armenia reported alcohol consumption in the past three months, followed by the Philippines at 67 percent. Men in Haiti are the least likely to consume alcohol: only 19 percent of men report having drunk an alcoholic beverage in the past three months.

In all countries except for Gabon, Uganda, Rwanda, the Philippines, and Haiti, urban men are more likely than rural men to drink. The biggest urban/rural difference in alcohol consumption is in Zambia, where 56 percent of urban men drink, as compared to 37 percent of rural men. Namibia and Kenya also have differences of about 10 percentage points between urban and rural alcohol consumption, where alcohol consumption is higher in urban areas, whereas in Rwanda, rural men are considerably more likely to consume alcoholic beverages than urban men (56 percent and 43 percent, respectively).

Never-married men are less likely to drink compared to the other marital status groups in all countries except for Mauritania, the Philippines, and the Dominican Republic. As with smoking, never-married men tend to be younger than those who are or have been married. Men who were once married but are currently either separated, divorced, or widowed tend to be the most likely to report consuming alcohol.

Table 5.3 Men's health behaviors by demographic background characteristics: alcohol consumption

<sup>xxx</sup> Drinking assessed for the past 7 days

<sup>b</sup> Ever-married men's survey

Table 5.4 shows the percentage of men who drink alcohol by education, occupation, and wealth index quintile. There is no clear association between alcohol consumption and level of education. Complete data are available for 14 countries. In five countries (Nigeria, Kenya, Burkina Faso, Zambia, and the Dominican Republic), the percentage of men who drink alcohol increases with level of education, but the opposite is true in four countries (Zimbabwe, Gabon, Uganda, and Haiti). There is no consistent pattern in the remaining countries. In all but three countries, the percentage of men who drink alcohol is lowest among men who are not working. In general, men in the professional/technical/managerial occupations and those in manual/other occupations report recent consumption of alcohol more frequently than men in other occupations or men who are not working at all. There is no clear pattern associated with the percentage of men who drink and the wealth index.

Table 5.5 shows the percentage of men who drink alcohol by selected gender attitudes. Twelve countries have data on the joint household decisionmaking indicator. In seven of those countries, men who say that decisions on large household purchases should be made jointly with a wife are more likely to report having consumed alcohol recently. For the remaining five countries (Malawi, Zambia, the Philippines, the Dominican Republic, and Haiti), there is no difference in alcohol consumption by whether or not respondents believe in joint decisions on large purchases. In some instances, the difference in alcohol consumption by decisionmaking preference is quite large. In Burkina Faso, men who say husbands should make joint decisions with their wives on large purchases are 69 percent more likely to have recently consumed alcohol than men who do not advocate shared decisionmaking. In Nigeria, those who believe in joint decisionmaking are 79 percent more likely to drink than those who do not, and in Mozambique, the corresponding difference is 43 percent.

Differences in alcohol consumption between men who agree with none of the five specified justifications for hitting a wife and men who believe in any of the five specified justifications for hitting a wife, where they exist, are fairly small (about 5 percentage points), and not consistent in direction. Differences in alcohol consumption between men who agree with a woman's right to refuse sex with her husband for all four reasons specified and men who disagree with any of the four reasons specified for refusal are likewise generally small. Where differences exist, they tend to reflect more alcohol consumption among men who agree with a wife's right to refuse sex; Zimbabwe in particular shows a difference in alcohol consumption of 22 percentage points between those who disagree with any of the reasons for a wife to refuse sex (28 percent) and those who agree with all four reasons (50 percent). Finally, alcohol consumption does not vary by attitudes about retaliating against a wife who refuses sex.

<sup>1</sup> Justifications given for a husband to hit his wife are as follows: If she goes out without telling him, if she neglects the children, if she argues with him, if she refuses to have sex with him, and if she burns the food.

<sup>2</sup> Specified reasons that a woman may refuse sex include the following: She knows her husband has a sexually-transmitted disease, she knows her husband has sex with women other than his wife/wives, she has recently given birth, or she is tired and not in the mood.

<sup>3</sup> Types of retaliations a husband may justify for his wife refusing to have sex are as follows: Get angry and reprimand her, refuse to give her money or other means of financial support, use force and have sex with her even if she does not want to, or go and have sex with other women.

<sup>b</sup> Ever-married men's survey

### 5.3 Sexually Transmitted Infections

Sexually transmitted infections (STIs) constitute a serious health problem, both by themselves and by their ability to increase susceptibility to or transmission of other diseases. For example, herpes simplex virus 2 is associated with HIV infection (Severson and Tying, 1999). Human papillomavirus is associated with cervical cancer (Bosch et al., 2002). Chlamydia trachomatis may be associated with male infertility (Gdoura et al., 2001), and several STIs, when passed from men to their female partners, are known to reduce female fertility or cause infertility. Controlling the spread of STIs by timely and appropriate treatment has been shown to reduce the incidence of HIV by as much as 40 percent (Grosskurth et al., 1995). For all of these reasons, it is critical that STIs be identified and treated.

In the DHS, men who have ever heard of STIs are asked first whether they have had an STI in the past year. Subsequent questions, asked regardless of whether the respondent had heard of an STI, focus on symptoms of STIs: whether in the past year the respondent has had a discharge from his penis, whether he has had a sore or ulcer on or near his penis, and whether he has had pain or a burning sensation during urination.

Some respondents may be reluctant to report that they have had an STI, or may not know they have an STI. Thus, the levels of infection presented here are likely underestimates. There are slight variations in how and of whom the questions on STIs were asked. In some countries, only those who reported having ever had sex were asked the questions on sexually transmitted infections; in other countries, only those who reported that they had a diagnosed STI in the past month were included in the numerator. Any country with a variation from the standard is marked with a corresponding footnote.

Table 5.6 shows the total percentage as well as percentages of men in each age group, in urban and rural areas, and in different types of unions who reported having had an STI or STI symptom in the past year. (Note: from this point forward, both diagnosed STIs and reported symptoms of STIs will be referred to as STIs).

In the SSA region, the proportion of men reporting an STI ranges from 2 percent in Rwanda to 10 percent in Gabon. Reported levels are much lower, less than 1 percent, in both Armenia and Kazakhstan. The two SSEA countries for which data are available are the Philippines (1 percent) and Bangladesh (9 percent). Prevalence in the LAC region ranges from 1 percent (the Dominican Republic) to 8 percent (Haiti).

The distribution of STIs by age generally has an inverted U-shaped pattern, with the youngest and oldest age groups typically being less likely than the middle age groups to report STIs. This likely reflects somewhat lower levels of sexual activity at the youngest and oldest ages. Urban-rural differences are small and inconsistent in direction. Only in three countries are there urban-rural differences of at least 5 percentage points: Cameroon and Zambia, where urban levels are higher, and Haiti, where more STIs are reported in rural areas. Men who are divorced or separated tend to be the most likely to report STIs.

Table 5.6 Men's health by demographic background characteristics: sexually transmitted infections

Percentage of all men who report a sexually transmitted infection (STI) or a symptom of an STI by age, residence, and marital status, Demographic and Health Surveys, 1995-2004

x In these countries, men in informal unions were categorized with men in married unions, and widowed men were categorized with divorced/separated men.

xxx Only those who reported having ever had sex were asked the questions on STIs.

xxx Only those who reported that they had a diagnosed STI in the past month were considered in the numerator.

& Category not included in the Cameroon survey.

na = Not applicable

Table 5.7 shows the percentages of men reporting an STI by education level, occupation, and wealth index. There is no consistent association between reporting an STI and level of education; any differences by education that do exist are small, though percent differences are large in some cases. Of the 32 countries that collected these data, the proportion of men reporting an STI increases with increasing education in nine countries, the proportion decreases with increasing education in seven countries, and there is no relationship between STIs and education in the remaining countries.

In 15 of 32 countries, men working in manual/other occupations are most likely to report an STI, while men in professional/technical/managerial jobs are least likely to do so. There is no consistent association between wealth index and reporting of STIs. A few countries demonstrate a negative association (Mali, Mauritania, and the Philippines), but in some countries the largest proportions of men reporting STIs are in the two wealthiest quintiles (Cameroon, Mozambique, Togo, Uganda, Benin, Chad, Burkina Faso, and Bolivia).

Table 5.7 Men's health by socioeconomic background characteristics: sexually transmitted infections

\* Figure suppressed since N < 25.

() indicates that figure should be interpreted with caution: N = 15-49.

<sup>xx</sup> Only those who reported having ever had sex were asked the questions on sexually-transmitted infections.

Table 5.8 demonstrates the relationship between men's report of having had a STI and selected indicators of men's attitudes toward women. Although the numerical differences are small, men who are more supportive of women's rights are generally less likely to report having had an STI in the past 12 months.

Table 5.8 Men's health by gender attitudes: sexually transmitted infections

## 6 Men and Families

The 1994 International Conference on Population and Development formally articulated the idea that population health and national development are best achieved when men fully participate in and take responsibility for their own sexual and reproductive health and that of their partners, as well as the health and well-being of their children (International Conference on Population and Development, 1994). In order for that to occur, however, communication between men and their partners about sexual and reproductive matters is necessary. Fathers may need to learn how best to help care for their child's health, and what benefits father-care confers upon children (Mezulis, Hyde, and Clark, 2004; Le Menestrel, 1999).

Recent DHS surveys have begun to ask a wider array of questions about men's participation in family dynamics and child health. This section of the comparative report describes indicators of male participation in family communication and child health care according to selected demographic, socioeconomic, and gender variables.

### 6.1 Men's Participation in Husband-Wife Communication

Communication between partners about sexual and reproductive health is critical. Each partner's sexual and reproductive rights must be respected, couples must work together towards only having as many children as they want, and both husbands and wives must mutually acknowledge the risks of HIV/AIDS and work together to avoid exposure to HIV. To measure the prevalence of such communication, the DHS questionnaire asks men whether they have communicated with their spouse/partner about contraception, ideal family size, and HIV/AIDS. Table 6.1 shows the percentages of men reporting each type of communication with their spouse.

#### *Discussion of Contraception*

In most countries, currently-married men were asked whether they discussed contraception with their wives in the past year. As noted in the table, in some countries, men were asked the number of times they spoke with their wives about contraception in the past 12 months. In other countries, men were asked if they spoke to anyone about contraception in the past year, and if so, who. They are counted for this indicator if they report having spoken to their wives.

In the SSA region, communication about contraceptive use is highest in East and Southern Africa, with Zimbabwe (85 percent) and Zambia (72 percent) demonstrating the highest levels of communication, followed by Rwanda (69 percent), Namibia (67 percent), and Uganda (59 percent). Over 50 percent of men have discussed contraception with their wives in the past year in Benin and Comoros.

The two countries in the NAAE region, Turkey and Kazakhstan, differ greatly in the proportion of men reporting having spoken with their wives/partners about contraception. Only 5 percent of husbands in Turkey reported communication about contraception, compared to 55 percent of men in Kazakhstan reporting the same.

In SSEA, 36 percent of Filipino men report spousal communication about contraception, while 45 percent and 55 percent of husbands in Indonesia and Nepal, respectively, report the same. The LAC countries also show wide variation in proportions of men communicating about contraception, ranging from 9 percent in Brazil to 89 percent in Peru.

#### *Discussion of Family Size*

Currently-married men were asked whether they had discussed with their partner the number of children they would like to have. In all countries with the exception of Mali (38 percent), over 50 percent of men reported having discussed an ideal family size with their partners. In SSA, Zambia and Zimbabwe again

demonstrate the highest levels of communication, with 78 percent and 86 percent, respectively, communicating with their wives about ideal family size. In the remaining countries, over 80 percent of men report discussing with their wives the number of children they would like to have, with the exception of Haiti, where the proportion is 64 percent.

<sup>1</sup> In Chad and Mauritania, only men with one wife were asked the questions on contraceptive use and desired family size.

<sup>2</sup> Variation on standard question about contraceptive use: In the past 12 months, how many times have you talked with your wife/partner about family planning?

<sup>3</sup> Variation on standard question about contraceptive use: In the past few months, have you talked to anyone about family planning? (Counted if husband reports talking to wife.)

## Discussion of HIV/AIDS

Men were asked whether they had ever discussed ways of avoiding HIV/AIDS with their spouses. In the SSA region, where AIDS has hit hardest, men are more likely to have discussed HIV/AIDS with their spouses than men in other regions. Men in Mauritania and Mali are the least likely in the region to

report communication with their wives on this topic, while more than 80 percent of men have discussed HIV with their partners in Zimbabwe, Cameroon, Uganda, Kenya, Malawi, and Zambia.

Of the remaining countries with data on this indicator, only in Haiti and the Dominican Republic do proportions of men who report discussing HIV/AIDS with their spouse/partner exceed 50 percent.

## 6.2 Men's Knowledge of Children's Health Care

In developing countries, diarrhea is a major killer, estimated to have killed 2.2 million people in 1998 alone, most of whom were children under 5 years of age (World Health Organization, 2000). Only a few countries have asked questions that assess men's knowledge of how to take care of a child who is sick with diarrhea.

Of these few countries, Malawian men are best informed about child health care practices in case of diarrhea: almost all men (97 percent) have heard of the local ORS (oral rehydration salts) packets, and 79 percent of men know that children with diarrhea should be given more to drink than usual. Knowledge of the local ORS packets is fairly high in Mozambique (87 percent) and Ghana (89 percent), but only 40 percent of men in Ghana and 51 percent of men in Mozambique know that children sick with diarrhea need more than usual to drink. Ghanaian men's misunderstanding of children's needs during a bout with diarrhea is dangerous: 35 percent of men believe that sick children should be given less than usual to drink. Restricting fluids during a bout of diarrhea can result in dehydration, which, if left untreated, can lead to the death of the child.

Similarly, in the Dominican Republic, 40 percent of men believe that children should get less to drink than usual, and only 45 percent of men believe they should get more. Eighty-one percent of Bolivian men have heard of the local ORS packets, and 69 percent know to give children more fluids than usual in case of diarrhea. Three-quarters of Nepalese men know that additional fluids during a bout with diarrhea are necessary.

Table 6.2 provides available survey data on men's knowledge about providing care for children with diarrhea.

Table 6.2 Men's knowledge of children's health care

Percentage of men who know the importance of maintaining hydration in a child sick with diarrhea, and percentage of men who have heard of the local oral rehydration solution packets, Demographic and Health Surveys, 1995-2005

<sup>a</sup> Only men who have had children were asked the question on hydrating children with diarrhea in Zambia.

<sup>b</sup> Ever-married men's survey

## 7 Summary and Conclusions

This report has documented both socioeconomic and demographic characteristics of male respondents to the DHS surveys in 40 developing countries, as well as males' attitudes, preferences, and behaviors relating to contraception, fertility, and health.

The data presented in this report show the expected large regional variations in the reproductive preferences and behavior of men. Although these findings have been shown before for currently-married men, this report also examined the regional variations in preferences and behaviors of never-married men. A key finding of this report in an era dominated by the specter of AIDS, for example, is that in all countries, never-married men (mostly youth age 15-24) are far more likely to know about modern contraceptive methods (particularly condoms) than they are to engage in sexual activity. This combination of knowledge and behavior suggests that most countries currently have a good foundation for the activities of youth-focused family planning and sexual health programs.

Another contribution of this report is its analysis of key indicators by the wealth index. Although the relationship between wealth and outcomes of interest is typically in the expected direction, the tables presented in this report allow for a closer investigation of the gradients of inequality that men experience for each outcome. Thus, the variation in knowledge of contraceptive methods among never-married men by the wealth index is minimal in Malawi, while it is considerable in Guinea. These results are useful in identifying subpopulations that would get the most benefit from programmatic interventions.

Other contributions made by this report include the presentation of comparable data on men's attitudes about gender roles; men's communication with their spouses about important health issues; and data on men's health-related behaviors regarding their own health and their knowledge of child health issues. The analysis of key indicators such as experience of STI symptoms according to gender attitudes suggests that gender attitudes do matter for men's health outcomes as well as women's. Encouraging change in men's understanding of women and their rights and social roles may be one path towards improved population health outcomes. The report demonstrated considerable variation in levels of couple communication about important health issues like HIV and family planning both within and across regions; this kind of country-specific information provides important guidance for program implementation. Similarly, the data presented on men's own health-related behaviors, such as smoking, allows policymakers to pinpoint where to target resources for intervention. The few countries that collected data on men's knowledge of how to care for children with diarrhea demonstrate the large variation in men's knowledge of how to care for a child with diarrhea. Again, these data serve as a signal to policymakers and those who implement programs that in some countries there is considerable need for fathers to be informed about how to care for a sick child.

As the analysis of trends in several countries demonstrates, sociodemographic indicators such as education and behavioral indicators such as engaging in higher-risk sexual activity can and do change over time—and often for the better. Past improvements, though, are not necessarily indicative of future performance. Continued efforts are required to maintain progress towards sustainable population and health goals for men and their families.

Note: Data are for all men except for the following:

Turkey 1998 – Husbands of eligible women

Indonesia 2003 – Currently married men; also, data do not indicate if men were married to 1 or 2+ wives

Nepal 2001 – Ever-married men

<sup>a</sup> Widowed category was not included in the Cameroon survey

<sup>b</sup> In Comoros 1996, "Currently in informal union" and "Widowed" were not included in the "Ever-married" category because they were assigned to the category "Never had sex" (var. MV531). In Comoros, men who did not know where to get a condom were skipped out on the question on number of partners.

<sup>c</sup> Means for the number of partners do not include wives.

<sup>d</sup> Information is missing on number of partners in 44 cases; they are not included in the denominator.

na = Not applicable

Peru 1996	205	332	1,554	2,092	203	329	1,551	651	1,353	63	17	2,095

Note: Data are for all men except for the following:

Turkey 1998 – Husbands of eligible women

Indonesia 2003 – Currently married men; also, data do not indicate if men were married to 1 or 2+ wives

Nepal 2001 – Ever-married men

<sup>a</sup> Widowed category was not included in the Cameroon survey

<sup>b</sup> In Comoros 1996, "Currently in informal union" and "Widowed" were not included in the "Ever-married" category because they were assigned to the category "Never had sex" (var. MV531). In Comoros, men who did not know where to get a condom were skipped out on the question on number of partners.

<sup>c</sup> Means for the number of partners do not include wives.

<sup>d</sup> Information is missing on number of partners in 44 cases; they are not included in the denominator.

na = Not applicable

<sup>a</sup> Husband survey

<sup>b</sup> Ever-married men's survey

<sup>c</sup> Currently-married men's survey. Also, the data do not tell if the men were married to 1 or 2+ wives.

<sup>#</sup> In these countries, the questions on contraceptive use were asked for most recent use only, which is in the past 12 months instead of in the current time.

Table 3.6bN (weighted) Current use of a modern contraceptive method among ever-married men by demographic background characteristics  
 Number of ever-married men who are currently using a modern method by age, residence, and marital status, Demographic and Health Surveys, 1995-2004

<sup>a</sup> Husband survey

<sup>b</sup> Ever-married men's survey

<sup>c</sup> Currently-married men's survey

<sup>o</sup> In these countries, respondents were asked about daily, rather than weekly, radio listenership.

<sup>#</sup> In these countries, the questions on contraceptive use were asked for most recent use only, which is in the past 12 months instead of in the current time.

Table 3.7bN (weighted) Current use of a modern contraceptive method among ever-married men by socioeconomic background characteristics  
 Number of ever-married men who are currently using a modern method by education, occupation, and wealth index, Demographic and Health Surveys, 1995-2004

<sup>1</sup> Justifications given for a husband to hit his wife are as follows: If she goes out without telling him, if she neglects the children, if she argues with him, if she refuses to have sex with him, and if she burns the food.

<sup>2</sup> Specified reasons that a woman may refuse sex include the following: She knows her husband has a sexually-transmitted disease, she knows her husband has sex with women other than his wife/wives, she has recently given birth, or she is tired and not in the mood.

<sup>3</sup> Types of retaliations a husband may justify for his wife refusing to have sex are as follows: Get angry and reprimand her, refuse to give her money or other means of financial support, use force and have sex with her even if she does not want to, or go and have sex with other women.

<sup>a</sup> Husband survey

<sup>b</sup> Ever-married men's survey

<sup>c</sup> Currently-married men's survey. Also, the data do not tell if the men were married to 1 or 2+ wives.

Table 5.1N (weighted) Men's health behaviors by demographic background characteristics: smoking

<sup>1</sup> Justifications given for a husband to hit his wife are as follows: If she goes out without telling him, if she neglects the children, if she argues with him, if she refuses to have sex with him, and if she burns the food.

<sup>2</sup> Specified reasons that a woman may refuse sex include the following: She knows her husband has a sexually-transmitted disease, she knows her husband has sex with women other than his wife/wives, she has recently given birth, or she is tired and not in the mood.

<sup>3</sup> Types of retaliations a husband may justify for his wife refusing to have sex are as follows: Get angry and reprimand her, refuse to give her money or other means of financial support, use force and have sex with her even if she does not want to, or go have sex with other women.

<sup>x</sup> In these countries, men in informal unions were categorized with men in married unions, and widowed men were categorized with divorced/separated men.

<sup>xx</sup> Only those who reported having ever had sex were asked the questions on sexually-transmitted infections.

<sup>xxx</sup> Only those who reported that they had a diagnosed STI in the past month were considered in the numerator.

<sup>xxxx</sup> Only those who reported symptoms (either an ulcer or discharge) were considered in the numerator.

<sup>&</sup> Category not included in the Cameroon survey

Table 5.7N (weighted) Men's health behaviors by socioeconomic background characteristics: sexually transmitted infections

Number of men for analysis of reporting of a sexually transmitted infection (STI) or a symptom of an STI, by education, employment, and wealth index, Demographic and Health Surveys, 1995-2004

Country	Education			Occupation				Wealth index					Number of men	
	None	Primary	Second-ary or more	Not working	PTM	Clerical, sales, services	Agri-culture	Manual, other	Lowest	Second	Middle	Fourth		Highest

<sup>1</sup> Justifications given for a husband to hit his wife are as follows: If she goes out without telling him, if she neglects the children, if she argues with him, if she refuses to have sex with him, and if she burns the food.

<sup>2</sup> Specified reasons that a woman may refuse sex include the following: She knows her husband has a sexually-transmitted disease, she knows her husband has sex with women other than his wife/wives, she has recently given birth, or she is tired and not in the mood.

<sup>3</sup> Types of retaliations a husband may justify for his wife refusing to have sex are as follows: Get angry and reprimand her, refuse to give her money or other means of financial support, use force and have sex with her even if she does not want to, or go have sex with other women.
